MULTIPLE-JOB HOLDING AMONG MALE WORKERS IN GREECE

Ilias Livanos[♦] and Alexandros Zangelidis[▲]

Abstract

This paper studies the incidence of multiple job-holding in Greece and contributes to the literature by examining its determinants, its variance across different regions and the effect of the business cycle on its occurrence. The empirical analysis highlights the importance of both pecuniary and non-pecuniary motives behind multiple job-holding, and reveals significant variations in its incidence across regions, with areas that have a large primary sector having higher multiple job-holding rates. Finally, multiple job-holding is found to be pro-cyclical, with the probability of holding a second job estimated to increase during economic expansions.

Keywords: Multiple-job holding, Greece, regions, business cycle

1. Introduction

Multiple job-holding is an area of economics that despite having attracted considerable attention over the last decade, still remains relatively under-researched. For instance, very little light is thrown on the regional aspects of multiple job-holding, and how its incidence varies across local labour markets, even though there are many theoretical reasons which make its investigation rather intriguing.

Holding more than one job is a very common practice in Greece as individuals often need to supplement the income they receive from their first job as wages in Greece are amongst the lowest in the European Union, (EU15)¹. As BALDWIN-EDWARDS and SAFILLIOS-ROTHSCHILD (1999) note “there is an endemic tendency towards multiple job holding [in Greece]” (p297). A paradigmatic example is the group of teachers for which taking a second job of private tutoring is a very common practice for supplementing their income (KANTAS and VASSILAKI, 1997). However, to the best of our knowledge there is not empirical investigation of its occurrence in the Greek labour market².

This paper aims to contribute to the existing literature in three main ways. First of all, it is the first economic examination of multiple job-holding in Greece. Second, it examines how its incidence varies across different regions, which remains a relatively under-explored area within labour economics. Third, it investigates the cyclicity of multiple job-holding focusing on how the business cycle, reflected at the current and lagged levels of regional unemployment, affects its occurrence. Greece seems to be an interesting case for investigating the above due to large employment and income regional disparities, the structures of the local labour markets, and the demographic composition of the labour force.

¹ See <http://www.eurofound.europa.eu/eiro/2002/09/feature/gr0209104f.htm>

² Exception is the early work of DAOULI and DEMOISSIS (1995) who investigated multiple-job-holding in the agricultural sector.

2. Theoretical Considerations of Multiple Job-Holding

Individual motives

Economic theory offers two main motivations for multiple job-holding. These are: hours constraints on the primary job, and heterogeneous jobs. According to the first motivation an individual may face a constraint on the number of hours that she or he can work in the primary job that in turn limits the earnings levels of this job. Thus, since the employer is unable to offer enough hours on the primary job, the individual may choose to start a second job in order to achieve his/her required income level.

According to the second motivation (heterogeneous jobs) individuals may also decide to take up a second job even though they do not face any hours-constraints on their main job. In that case, multiple job-holding may arise because the hours of labour supplied to the two jobs are not perfect substitutes, and thus individuals choose to take up a second job for reasons that are not connected to primary job hours or earnings. These reasons might include: learning about new occupations or gaining training, engaging in activities of interest, gaining job satisfaction not received from the primary job, gaining credentials and experience to acquire a higher paying second job; or maintaining flexible work schedules.

Standard economic theory assumes that an individual's labour supply decisions, on both the primary and secondary jobs, are based on utility-maximising behaviour. An hours-constrained employee works less hours in his/her primary job than the required in order to reach the optimum income level that maximises his/her utility. For the hours-constrained employee, the hours of work in the primary job are no longer a choice, and thus there is no alternative to starting a second job (CONWAY and KIMMEL, 1998).

Early empirical work on multiple job-holding was primarily focused on the hours constrained motivation. The first theoretical and empirical treatment was carried out by SHISKO and ROSTKER (1976) who found that the supply of labour to a second job fell as primary job earnings increased. Similarly, HAMEL (1967) found that the level of a worker's earnings determines the propensity of multiple job-holding and as

the level of earnings rises the incidence of multiple job-holding declines. GUTHRIE (1969) investigated moonlighting among teachers in the U.S. and found evidence consistent with the general belief that multiple job-holding serves primarily to improve living standards. Moreover, KRISHNAN (1990) found that longer hours and higher income in the primary job deters multiple job-holding, adding further support to the hours constraints motive for moonlighting.

More recent studies have begun to recognise different motives and other issues of interest. For instance, the dynamics of moonlighting were investigated by KIMMEL and CONWAY (2001) for the U.S. and BÖHEIM and TAYLOR (2004) for Great Britain. They argued that those who have more than one jobs due to hours constraint would be expected to have shorter “moonlighting spells” compared to those with a different motives (e.g. those who have heterogeneous jobs). Their study revealed evidence of multiple motives with the constraint motive being the most common. In addition, they also found that multiple job-holding is persistent over time and concluded that hours constraints is unsatisfactory as an explanation for moonlighting.

PAXSON and SICHERMAN (1996), examined the patterns of mobility into and out of second job and concluded that multiple job-holding is a dynamic process with most workers experiencing it at some point in their working lives, as well as that the hours constraints explanation for moonlighting fails to account for the fact that over time workers can avoid hours constraints by searching for new jobs.

AVERETT (2001) investigated gender differences, but did not find any substantive differences in the factors causing males and females to have multiple jobs. BELL *et al.* (1997), examined the idea that multiple job-holding acts as a “hedge” against unemployment but little evidence was found to support this motive. Finally, KRISHNAN (1990) investigated whether a husband’s decision to moonlighting is affected by his wife’s decision to work, and concludes that increased labour force participation by wives deters moonlighting.

The regional aspect of multiple job-holding

An area that has been relatively under-researched in the literature is the effect of region of residence on multiple job-holding. Nevertheless there are various theoretical reasons relating region of residence and number of jobs. For instance, less populated areas are often lacking in economies of agglomeration pushing their workers to rely on job alternatives (LEVETAN and FELDMAN 1991). Similarly, lower wages, public spending and demand for labour make multiple job-holding a strategy of vital importance (MILLER 1987). Thus, the distinctive character of regional labour markets constitutes an important factor in explaining dual job-holding. MONK and HODGE (1995) argue that urban and rural areas behave differently due to their distinctive economic structures, such as differences in transportation systems, wage levels, and the propensity for part-time work.

However, the most crucial aspects of regional labour markets are the employment opportunities and options available to workers as well as the efficiency of institutional mechanisms on disseminating job-related information and providing human resource related programs (BRIDDS 1986). In general, rural regions have narrow industrial bases, smaller numbers of employers, and higher levels of self employment (HODGE 2002). Similarly, GREEN (1997) suggests that individuals without higher qualifications are those whose employment is most affected.

These regional and urban-rural differences have important implications regarding the incidence of multiple job-holding. DICKEY and THEODOSSIOU (2006) suggest that dual job-holding is more relevant to self-employed workers as a way of optimising over the mean and variance of income. Thus, it is worth investigating how the incidence of multiple job-holding varies across regions with different economic and employment structures.

Multiple job-holding and unemployment

At a macro level there are various studies examining the cyclicity of multiple job-holding in general and how it is affected by the levels of unemployment in particular. From a theoretical standpoint there is no a priori reason why multiple job-holding

should either be expected to be pro-cyclical or counter-cyclical (AMUEDO-DORANTES and KIMMEL, 2005). From a demand-side point of view one would expect multiple job-holding opportunities to be restricted during an economic recession, whereas from the supply side one may anticipate that individuals may decide to get a second job in order to ensure an uninterrupted and continuous flow of income during a downturn of the economy. This ambiguity is reflected in a number of empirical studies that present mixed evidence, arguing that multiple job-holding shows both pro-cyclical and counter cyclical patterns. On the one hand there is evidence that the rates of multiple job-holding drop during periods of low unemployment (EMPLOYMENT POLICY INSTITUTE³, 1999), and on the other hand other empirical evidence (AMUEDO-DORANTES and KIMMEL, 2005) suggests that the chances of multiple job- holding increase during periods of economic expansion as there is higher job availability.

Nevertheless, in both cases the incidence of multiple job-holding is affected by the state of the regional labour market. For instance, PARTRIDGE (2002) found evidence of pro-cyclicality and argues that 'moonlighting appears to be a regional labour market shock absorber' (p. 438). Thus, an interesting aspect of multiple job-holding is to investigate how its incidence is affected by the current and lagged levels of regional unemployment.

3. Regional features of the Greek labour market

One of the most distinctive characteristics of the Greek economy is the strong persistence of regional differences. In particular, the divergence of Greek regions is much stronger than other peripheral areas of Europe, such as Spain and Portugal. Nevertheless, research on the convergence hypothesis concludes in mixed results. A body of evidence (SIRIOPOULOS and ASTERIOU, 1998; TSIONAS, 2002) suggests lack of income convergence among Greek regions, and the existence of economic dualism between southern and northern regions. On the other hand, a study by MICHELIS *et al.* (2004) does not reject the idea of regional convergence. Regarding unemployment, rates vary greatly across regions of the country. The implications of

³ Cited in AMUEDO-DORANTES and KIMMEL (2005)

regional variation of unemployment for the Greek economy are significant as Greece has the highest percentage (73%) of the labour force living in regions with an unemployment rate above the national average amongst OECD countries (OECD, 2005). The large regional unemployment disparities were explored in a study by Livanos (forthcoming) that did not find evidence of wage rigidity, which is quite interesting since Greece has a rather inflexible labour market and one would expect the opposite. Livanos suggested that this is due the large regional disparities and the distinctive features of the local labour markets. All the above, suggest strong regional differences in the Greek economy. These differences, apart from problems of immigration and other sociological and historical explanations, have also been attributed to ineffective planning, which is mainly an outcome of lack of relevant experience in comparison to rich countries (SIRIOPOULOS and ASTERIOU, 1998).

The large regional unemployment disparities are in fact on the most striking features of the Greek labour market. A study by PUGA (2002) classifies Greece in the group of countries with the largest regional disparities in Europe. **Table 1** presents the regional unemployment rate for the period 1999-2004. As can be seen, the differences in regional unemployment are quite large. To illustrate, Western Macedonia, on average, has an unemployment rate around two times higher than Crete. In general, unemployment is concentrated mainly on northern and central regions. On the other hand, southern regions of Greece seem to be less affected by unemployment. The high rates of unemployment in Northern and Central Greece can be attributed to the contraction of the manufacturing and the agriculture sectors. This is evident in **Figure 1** where in regions like Western and Eastern Macedonia, Thessaly and Central Greece there is a relatively large primary and secondary sector. Regarding manufacturing, the pressures of international trade and the attractiveness of the low paid workforce in countries of Eastern Europe have led many industrial units, operating mainly in regions of Northern Greece and Central Greece, either to close down or move elsewhere. This, together with the shrinkage of the agricultural sector, which has traditionally been a large part of the Greek economy, have resulted in the rise of unemployment in these particular regions over the last twenty years. Regarding Southern Greece, the levels of unemployment have

remained at low levels as these regions rely heavily on tourism which remains at high levels while they have experienced high levels of economic growth over the last decades. Typical examples of such regions are Crete and Ionian islands that have a relatively strong tertiary sector (**Figure 1**).

Figure 2 shows how the regional workforce is distributed across self-employed, family workers, and employees (wage-earners). A key observation of **Figure 2** is that regions (excluding the urban regions, i.e. Attica and Central Macedonia) where the level of family workers is fairly high (like in Eastern Macedonia, and Thessaly), unemployment rate is relatively high. This is indicative of the structures of the trends of the Greek economy, where the role of self-employment and small family business is central and is often seen as safety net against unemployment.

The multiple job-holding rates in the 13 regions are presented in **Figure 3**. Interestingly, there is notable variation on the incidence of dual job-holding across geographical areas, with a higher proportion of individuals in Crete, Eastern and Western Macedonia, Peloponnese, Thessaly and Central Greece reporting having a second job count. This is true for both male and female workers, although the rates are significantly higher for males.

4. Data and methods

The analysis presented in this section draws on micro data from the Labour Force Survey (LFS), and in particular, annual cross-sections for the years 2000-2004 (spring quarter). The Greek LFS is conducted by the National Statistical Service of Greece (ESYE). Since 1998, the LFS is being conducted four times per year in order to meet the standards set by Eurostat. The questionnaire used is comprised of approximately 100 questions and both the questions and the definitions used are based on the European LFS (see EUROPEAN COMMUNITIES, 2003). The sample of the survey is 30,000 households and includes 80,000 observations approximately. Since the LFS is a sample survey, ESYE follows weighting procedures that are accordance with EU

guidelines⁴. The five individual datasets were pooled together into a unique one. For the purposes of our analysis only male individuals, aged 25 and over, who are either self-employed, employed (wage earners) or family-business employees, both part-time and full-time, are utilized. This results to a sample of 89,374 observations.

The data on wages is available only for employed individuals and refers to the net income from individuals' primary job. The wage variable in the LFS questionnaire distinguishes 6 income bands for the years 2000, 2001 and 2002 and 8 income bands for 2003 and 2004. For our purposes the median wage of each band is calculated. Regarding the region variable, it adopts the 2 level Nomenclature of Territorial Units for Statistics (NUTS), and defines 13 Peripheries of Greece. NUTS-3 level detail, that would increase the variation in the sample, is not available in the Greek LFS micro-data due to the anonymization process of ESYE. As for the unemployment variable, the analysis utilizes rates of unemployment for each of the 13 regions separately (**Table 1**). Finally, the weighted population variable, provided by ESYE, is applied to our analysis in order to obtain the total population of the labour market variables presented in this paper.

Table 2 reports demographic and job characteristics for the sample of individuals, and for single job-holders and multiple job-holders separately. The level of statistical significance of the difference in the means of the two groups is also provided in the last column. The reported level of second job-holding is around 4 percent, which is surprising low and well below the corresponding rates in other EU countries (see EUROSTAT LFS⁵). The main driver of this situation is the notably high level of unrecorded activity, which reasonably prevents individuals from reporting it during the LFS interview. For instance, *EUROFOUND*⁶ (2007) observes that un-recorded activity in Greece is very widespread and it accounts for about 25 per cent of the total economic activities. Similarly, previous studies of LIANOS *et al.* (1996) and KANELLOPOULOS (1992) estimated that the informal sector accounts for about 30-35

⁴ For a description of ESYE's weighting procedures see EUROSTAT (2006).

⁶ See <http://www.eurofound.europa.eu/emire/GREECE/HIDDENECONOMY-GR.htm>

per cent of GDP. These high rates of “hidden economy” can be explained by tax evasion, the high rates of unemployment, and the large share of people working in agriculture, which is an industry that employs a high proportion of undeclared workers (DELL’ ANNO *et al.*, 2007). Similarly, the exceptionally high rates of self-employment and unpaid family work operate in the same direction. Consequently, the levels of undeclared employment remain at very high levels, while the groups that are most affected are those with limited bargaining power in the labour market. In particular, the groups whose employment services are often not recorded are immigrants, young people, and low skilled workers who might agree to work without being recorded under the fear of unemployment. For instance, LAZARIDES and ROMANISZYN (1998), who analysed the extent of undocumented employment of Albanians and Polish in Greece, note that “the actual number of Albanian and Polish undocumented workers is difficult to estimate accurately and remains a topic of great controversy and speculation” (p.18). Thus all the above result into the low rates of recorded multiple job-holding in the LFS questionnaire. The suggested under-reporting of the multiple job-holding rates in the Greek LFS probably makes the identification of the determinants/motives behind this labour market behaviour more difficult due to the restricted information being available to the researchers.

Multiple job-holders, compared to single job-holders, tend to be more senior, and are more likely to be married, heads of the household, and of Greek origin. Furthermore, a higher percentage of manual workers appears to hold a second job, while the opposite is true for the low-skilled non-manual workers. Interestingly, the reported incidence of multiple job-holding is higher among the individuals working in the primary and secondary sector and lower for those employed in the tertiary sector. Finally, there are important regional differences in the second job-holding rates, with more than 50 percent of the multiple job-holders residing in the regions of Crete, Central Macedonia and Peloponnese.

As highlighted in the earlier review, one of the main reasons individuals hold a second job is financial need. Multiple job-holding is viewed as a survival strategy for those who cannot earn sufficient income in their primary job. Indeed, multiple job-

holders reported lower average earnings from their primary job, which is consistent with the financial need motive for second job-holding. Furthermore, a higher percentage of individuals who hold a second job appear to prefer to work more hours in their current job, compared to single job-holders. An indication that hours-constrained individuals currently resolve to holding a second job in order to overcome possible labour supply restrictions they face in their primary employment. Finally, the comparison between the two groups of workers reveals that a lower proportion of second job-holders has a permanent contract, suggesting that higher job insecurity may act as a motivation for individuals having two jobs.

5. Empirical Analysis

The decision to hold a second job is modelled and estimated here for all male workers⁷. The regressors used to explain multiple job-holding include individual characteristics (age, marital status, head of household, and nationality); job-related information (self-employed, family-employed, full-time/part-time job, preferences over working hours, public/private sector, industry sector, occupation); regions; regional unemployment (current and lagged) and year dummies. The model is estimated using a logit estimator with robust standard errors and the derived marginal effects are presented in **Table 3** (first column). A convenient way of interpreting the findings is to examine whether a specific characteristic makes an individual more likely to hold a second job. The results reveal some important findings regarding the reasons why individuals may get a second job, and the effects of regional unemployment and the structure of local economies on the incidence of multiple job-holding.

Looking at the demographic profile of the people who are likely to hold a second job, the findings suggest that married individuals and those who are heads of the household are more likely to hold a second job. For those individuals it appears that multiple job-holding may be a way to deal with their increased family needs and

⁷ Women's decision to hold a second job is a more complex issue to examine since it requires controlling for their labour market participation overall and also their role in the household before being able to make inference of their motives behind multiple job-holding. Restrictions in the data available to the authors do not allow the identification of valuable household characteristics (e.g. spouse's employment status). As a result, female individuals are excluded from the analysis.

financial commitments. Individuals aged between 35 and 44 are found to be more likely to have a second job, compared to young people (aged between 25 and 34), while for the other age groups there are no significant differences. This finding seems reasonable as individuals of the older group have more financial commitments, while individuals of the younger group often receive aid from their families, due to the strong family bonds in Greece, in order to face their financial constraints. Finally, immigrants are found to be less likely to hold a second job, compared to natives. A finding that should probably be treated with caution, since there may be high under-reporting, as indicated in the discussion above.

Regarding the characteristics of the primary job and the decision to hold a second job, individuals who would like to work more hours in their current job are more likely to have a second job, a finding in line with the hour-constraints motives. Full-time employees exhibit lower multiple job-holding, probably because of time allocation restrictions they may face and possibly due to the job security they may enjoy. Compared to employed individuals, those working in family businesses and self-employed individuals are more likely to hold a second job. Typically self-employment and family businesses may be regarded as more responsive to the business cycle, especially recessions. Therefore individuals in this kind of employment may hold a second job as a way to maintain a continuous flow of income and to minimise their exposure to the fluctuations of the economy. Also, the incidence of multiple job-holding is estimated to be higher among those employed in the public sector, compared to the private sector. This can be explained by the nature of the Greek public sector and its good working conditions, in terms of working hours, which may allow its employees to take up a second job. Furthermore, non-manual workers are more likely to hold a second job compared to manual workers. In addition, compared to those employed in the tertiary sector, individuals employed in the primary sector are more likely to hold a second job, followed by those working in the secondary sector. Wages in agricultural jobs, fishery and aquaculture tend to vary significantly over time, due to external factors like the weather condition and production restrictions, introduced by the government or EU regulations. Therefore, multiple job-holding may be an important means to the

individuals employed in these sectors of ensuring a stable flow of labour income. Further to this, this finding can be explained if one considers the high levels of self-employment in the primary and secondary sectors.

The differences in the incidence of multiple job-holding across the industry sectors are reflected at regional levels as well. Areas with developed primary sector, like Crete, Eastern Macedonia, Thessaly, and Peloponnese (**Figure 1**), are found to have higher multiple job-holding rates, compared to the reference region of Attica that has a relatively small primary sector. This can be explained by the structures of the local economies, which are dependent on the primary sector where businesses are generally organized along the lines of small family business that allow for distinctively high rates of self employment and family workers, which, as discussed above, have very high rates of multiple job-holding.

The effect of the business cycle on the incidence of multiple job-holding is explored with the inclusion of current and lagged regional unemployment in the estimated model. The results, in line with other studies in the literature (AMUEDO-DORANTES and KIMMEL, 2005; PARTRIDGE, 2002), suggest that multiple job-holding is procyclical, since the probability of moonlighting is found to increase during economic expansions (lower unemployment rate). This may be interpreted as an indication that job availability may play an important role in explaining multiple job-holding phenomenon.

In order to further explore the effect of industry sectors and regions on the probability of holding a second job, the model is re-estimated separately for each industry sector. The industry-regions interaction effects reveal some interesting patterns, particularly in the primary sector. The estimates on individuals working in the primary sector (**Table 3**, second column) indicate that there is significant regional variation in the incidence of second job-holding. Individuals in regions with developed primary sector, like Western Greece, Peloponnese, Thessaly, Epirus and Eastern Macedonia, are found to be less likely to hold a second job compared to those in Attica (the region with the smallest primary sector). This finding seems to

contradict the general feeling that multiple job-holding is more likely to occur in agricultural areas. However, it does not come as a surprise since these regions have considerably high rates of unemployment, and thus the employment opportunities are fewer than in Attica, which is the centre of economic activity in Greece. Thus this finding is in support of the pro-cyclical of multiple job-holding. Another interesting finding for the individuals in the primary sector is the large effect of working in the public sector on the probability of holding a second job. Although, individuals in the public sector are found to be more likely to have a second job the effect is significantly larger for those in the primary sector. Regarding the individual estimates for those employed in the secondary and tertiary sector (**Table 3**, third and fourth column), the estimates are quite similar to the overall estimates (**Table 3**, first column).

In the Greek LFS, information regarding some important aspects of the primary job (namely wages, length of contract and information on shifts) is available only for employed individuals and not for self-employed or those working in family businesses. Therefore, in order to examine further the motivation behind this labour market behaviour, the decision to hold a second job is re-estimated with the focus restricted only on employed individuals (**Table 3**, last column). As expected, wages are estimated to have a negative effect on multiple job-holding, supporting the financial motives hypothesis. However, financial motives alone are not sufficient to explain multiple job-holding. Multiple job-holding may be seen as a hedging strategy against job insecurity. This is indicated by the fact that individuals with temporary or fixed contracts in their primary job, compared to individuals in permanent jobs, are more likely to have a second job. Finally, individuals working shifts in their primary job are found less likely to have a second job.

6. Conclusion

This paper studied the multiple job-holding phenomenon in the context of the Greek labour market, which is characterised by high levels of agricultural activities. The aim of this paper was to contribute to the relevant literature by examining the determinants of second job-holding, its variance across different regions and the

effect of the business cycle to its occurrence. Greece, due to the large regional disparities, the structures of the local labour markets, and the demographic composition of the labour force, provide an appropriate context for investigating the above. The empirical analysis, based on data from the Greek Labour Force Survey, highlighted the importance of both pecuniary and non-pecuniary motives behind multiple job-holding. In particular, individuals were found to hold a second job not only to ensure a continuous flow of income to the household and deal with financial hardships, but as a hedge against job insecurity as well. The study also revealed significant variations in the incidence of multiple job-holding across regions, with areas with intense primary sector, like Crete, Eastern Macedonia, Thessaly, and Peloponnese, having higher multiple job-holding rates than non-rural areas, such as Attica and Central Macedonia, whose economic activity is oriented towards the service sector. Thus, this paper aims to highlight the importance of the nature of the local economies in explaining multiple-job-holding patterns. Finally, this study investigated the cyclicity of multiple job-holding and found evidence that second job-holding increases as the levels of unemployment decline. This finding, suggests that multiple-job-holding is pro-cyclical as it is related to the number of job opportunities that are available to workers. In particular, in regions where the levels of unemployment are low the incidence of multiple-job-holding was found to be higher.

The findings of this study implicate the need for further regional development in Greece, aiming to reduce the observed regional income and employment disparities. These could be driven by encouraging the development of the service sector in rural areas as well as the decentralization of the public sector across regions. Such developments would enhance the economic situation of residents of rural areas and provide them a form of security against unemployment.

The analysis of this study provided some interesting findings regarding dual job-holding in the Greek labour market. In considering this important labour market phenomenon the authors identified some possible avenues for future research. One thing that became apparent is the need for a more systematic collection of data that

would enable researchers to further investigate issues like the motives behind multiple job-holding. Furthermore, research on the occupational choices and duration of second job spells, as well as, the effect of second jobs on individuals' future labour market behaviour (e.g. job mobility, occupation/career changes) could provide a better understanding on dual job-holding and labour market dynamics overall.
