The Pure Logic of Value, Profit, Interest

Egmont Kakarot-Handtke

Abstract

Standard economic models are based on axioms that epitomize the fundamental behavioral assumptions. This approach is not conducive to convincing results. The suggested change of perspective is guided by the question: what is the minimum set of propositions for the consistent reconstruction of the evolving money economy? We start with three structural axioms and determine their real world implications. The claim of generality entails that it should be possible to demonstrate that well-understood parts of theoretical economics fit consistently into the structural axiomatic framework. We focus here on the classical theory of value as expounded by J. S. Mill.

JEL B12, B41, D00, E43

Keywords New framework of concepts, Structure-centric, Axiom set, Labour theory of value, Structural value theorem, Profit, Distributed profit, Rate of interest, Reproducibility

J. S. Mill clearly enunciated the question than stands at the beginning of any and every scientific inquiry:

What are the propositions which may reasonably be received without proof? That there must be some such propositions all are agreed, since there cannot be an infinite series of proof, a chain suspended from nothing. But to determine what these propositions are, is the *opus magnum* of the more recondite mental philosophy. (Mill, 2006b, p. 746), original emphasis

Where and when the axiomatic method originated is uncertain. We know about it particularly from Euclid. It is certain, however, that in economics axiomatization commenced with Adam Smith (Hollander, 1977) and Senior:

It [the axiomatic method] was introduced to economics in A.D. 1836 by Nassau William Senior in his *Outline of the Science of Political Economy* and is today more or less consciously adopted by most economic theorists as the way of theorizing in economics. (Stigum, 1991, p. 4)

Euclid's path runs through the classical school (Halévy, 1960, p. 494), the neoclassical school (Jevons, 1911, p. 21) and reached an unprecedented level of Walrasian abstraction in the 1960s (Debreu, 1959, p. x). Whether the project of Wald, von Neumann, Debreu, Arrow, Hahn, McKenzie, and others (Ingrao and Israel, 1990), (Leonhard, 1995), (Weintraub, 1998) has met with success is no longer an open question. It is plain that 'anything based on this mock-up is unlikely to fly' (Hahn, 1981, p. 1036), see also (Ackerman, 2004), (Kirman, 1989, p. 126).

Keynes, as so often, perspicuously articulated the challenge:

The classical theorists resemble Euclidean geometers in a non-Euclidean world Yet, in truth, there is no remedy except to throw over the axiom of parallels and to work out a non-Euclidean geometry. Something similar is required to-day in economics. (Keynes, 1973, p. 16)

The crucial point is not axiomatization per se but the choice of axioms. One cannot *not* axiomatize but one can practice it imaginatively or mechanically, rigorously or sloppily, systematically or haphazardly, precisely to the point or beside it. As Clower put it:

My opinion continues to be that axiomatics, like every other tool of science, is no better than its user, and not all users are skilled. (Clower, 1995, p. 308)

The thesis to start with suggests itself: neither neoclassical nor Keynesian economics possess a qualified axiomatic basis. Heterodox economists as complementary group mostly rebut the 'deductivist Euclidean methodology' recommend a more pluralistic approach, and propose to give up the 'Euclidean hope' (PålssonSyll, 2010, p. 52).

But from the argument that the neoclassical behavioral axioms are unqualified does not logically follow that the axiomatic method is defective. An outstanding proponent of axiomatization like Poincaré simply did not accept Walras's hypotheses of selfishness and farsightedness as axioms (Kirman, 2009, p. 82). It only follows that some economists have not applied the method correctly, for whatever reasons (Hudson, 2010, p. 15-16). The point at issue is the real world content of axioms.

The second thesis says: human behavior does not yield to the axiomatic method. A behavioral axiom is a methodological oxymoron (cf. Cairnes 1875, pp. iv-v). Yet the axiomatization of the economy's basic structure is feasible. Accordingly, the objective is to establish a formalism of maximum structural simplicity and generality. We start with an axiom set that is free of any behavioral specifications and subsequently approach the complexity of the real world by a process of consistent differentiation. The claim of generality entails that it should be possible to demonstrate that some well-understood parts of theoretical economics can be explicitly connected to the structural axiom set. We focus here on J. S. Mill, 'the most distinguished expositor' (Cairnes) of the classical theory of value, because he holds a nodal position at the crossroad of economic theory and methodology. Mill's answer, to be sure, is historical. His question, though, how it comes about that the value of commodities most of the time exceeds their cost of production and thereby keeps the market system going is topical.

The present paper has two parts. In the first, the logical interdependencies of the key variables that formally embody the business and the household sector and the markets in between are expounded. In the second, the real world implications with regard to the theory of value are made explicit. The analytical starting point is given with the structural axiom set in section 1. In sections 2 to 6 the structural value theorem, the profit ratio, and the rate of interest are derived for the competitive structure. The congruence and difference with the classical labour theory of value is highlighted. Section 7 concludes.

Although Mill propagated the axiomatic method he actually neither formalized his behavioral principle nor the theory of value. Hence Mill offers the starting point for both behavioral and structural axiomatization. The one route has been taken by neoclassical economists the other is followed here.

1 Axioms and Definitions

The first three axioms relate to income, production, and expenditures in a period of arbitrary length. For the remainder of this inquiry the period length is conveniently assumed to be the calendar year. It can be shown that the applicability of the axiom set does not depend on the chosen period length. Simplicity demands that we have at first one world economy, one firm, and one product. Quantitative and qualitative differentiation is obviously the next logical step after having worked out the implications of the following three axioms.

Total income of the household sector Y is the sum of wage income, i.e. the product of wage rate W and total working hours L , and distributed profit, i.e. the product of dividend D and the number of shares N .

$$Y_t = W_t L_t + D_t N_t \quad (1)$$

Output of the business sector O is the product of productivity R and working hours.

$$O_t = R_t L_t \quad (2)$$

Consumption expenditures C of the household sector is the product of price P and quantity bought X .

$$C_t = P_t X_t \quad (3)$$

A set of axioms cannot be assessed *ex ante*; it is a *tentative* formal starting point. The assessment comes on the next stage with the interpretation of the logical implications of the formal world and the comparison with selected data and phenomena of the real world. Axioms should have an intuitive economic interpretation (von Neumann and Morgenstern, 2007, p. 25). The economic meaning is rather obvious for the set of structural axioms. What deserves mention is that total income in eq. (1) is the sum of wage income and *distributed profit* and not of wage income and profit. Profit and distributed profit are quite different things that have to be thoroughly kept apart.

By choosing *objective* structural relationships as axioms behavioral hypotheses are not ruled out. On the contrary, the structural axiom set is open to *any* behavioral assumption and not restricted to the standard optimization calculus.

Definitions are supplemented by connecting variables on the right-hand side of the identity sign that have already been introduced by the axioms (Boylan and O’Gorman, 2007, p. 431). They add no content to the set of axioms but merely facilitate the use of symbols. New variables are introduced with new axioms. With (4) factor income Y_F , which is at the moment identical with wage income, and distributed profit income Y_D is defined:

$$Y_{Ft} \equiv W_t L_t \quad Y_{Dt} \equiv D_t N_t \quad (4)$$

With (5) the expenditure ratio ρ_E , the sales ratio ρ_X , the distributed profit ratio ρ_D , and the factor cost ratio ρ_F is defined:

$$\rho_{Et} \equiv \frac{C_t}{Y_t} \quad \rho_{Xt} \equiv \frac{X_t}{O_t} \quad \rho_{Dt} \equiv \frac{Y_{Dt}}{Y_{Wt}} \quad \rho_{Ft} \equiv \frac{W_t}{P_t R_t} \quad (5)$$

The axioms and definitions are consolidated to one single equation:

$$\frac{\rho_F \rho_E (1 + \rho_D)}{\rho_X} = 1 \quad |t \quad (6)$$

The *period core* (6) as absolute formal minimum determines the interdependencies of the measurable key ratios for each period. The period core is purely structural, i.e. free of any behavioral assumptions, unit-free¹ because all real and nominal dimensions cancel out, and contingent. Contingency means that it is open until explicitly stated which of the variables are independent and which is dependent. The form of eq. (6) precludes any notion of causality; it simply states the interdependence of the key ratios.

The factor cost ratio summarizes the internal conditions of the firm. A value of $\rho^F < 1$ signifies that the real wage is lower than the productivity or, in other words, that unit wage costs are lower than the price or, in still other words, that the value of output exceeds the value of input. In this case the profit per unit is positive. Then we have the conditions in the product market. An expenditure ratio $\rho^E = 1$ indicates that consumption expenditures are equal to income and a value of $\rho^X = 1$ of the sales ratio means that the quantities produced and sold are equal in period t or, in other words, that the product market is cleared. In the special case $\rho^E = 1$ and $\rho^X = 1$, that invokes the notion of an equilibrium with market clearing and budget balancing, the profit per unit is determined solely by the distributed profit ratio ρ^D . In one sentence: the period core covers the key ratios about the firm, the market, and the income distribution and determines their interdependencies. The period core represents the pure consumption economy, that is, no investment expenditures, no foreign trade, and no taxes or any other state activity.

2 The Structural Value Theorem

The axioms and definitions have first to be differentiated for two firms. This formal exercise is referred to the appendix. For the relative prices of two products then follows directly from eq. (43) in combination with (35):

$$\frac{P_1}{P_2} = \frac{R_2 L_2 C_1}{R_1 L_1 C_2} \quad \text{if} \quad \rho_{X1} = \rho_{X2} = 1 \quad |t \quad (7)$$

If the markets for both products are cleared the price ratio is inversely proportional to the ratio of productivities and the ratio of labor inputs and directly proportional to the ratio of the consumption expenditures for the two products. This implicates a soft budget constraint, that is, the sum of consumption expenditures $C_1 + C_2$ needs in the general case not be equal to income Y . For the special case of budget balancing, i.e. $\rho_{E1} + \rho_{E2} = 1$, it follows from eq. (7):

$$\frac{P_1}{P_2} = \frac{O_2}{O_1} \frac{1}{\frac{1}{\rho_{E1}} - 1} \quad \text{if} \quad \rho_{X1} = \rho_{X2} = 1 \quad |t \quad (8)$$

¹ “This procedure is in accordance with the principle of objectivity requiring that the whole theory and its interpretations have to be independent of the choice of the units of measurement. And this requirement is met, if the theory is unit-free, the necessary condition stated in Buckingham’s II-theorem.” (Schmiechen, 2009, p. 176)

Relative prices are equal to the inverse relation of the outputs of both firms multiplied with a factor that depends on the expenditure ratio for product₁ which is now complementary to the expenditure ratio for product₂. For the special case with total expenditures divided equally between the two products, i.e. $\rho_{E1}=0.5$, relative prices are equal to the inverse relation of the outputs. Or, as commonplace economics always had it (Niehans, 1994, p. 15), the relatively abundant product is cheap and the relatively scarce product is dear. If, on the other hand, outputs are equal, then the relative price of product₁ varies directly with the expenditure ratio ρ_{E1} .

Relative prices depend according to eq. (8) on the *objective* ratio of outputs, i.e. on supply, and on the *subjective* partitioning of consumption expenditures, i.e. on demand. Since we have from the standard theory of consumer demand the marginalistic behavioral condition that the marginal rate of substitution *MRS* be equal to the price ratio we are in the position to synthesize the structural formalism and the marginalistic behavioral assumption. From the definition of the expenditure ratio (5) follows:

$$\frac{\rho_{E1}}{\rho_{E2}} = \frac{\frac{C_1}{Y}}{\frac{C_2}{Y}} = \frac{P_1 X_1}{P_2 X_2} \quad |t \quad (9)$$

When, by applying the rule $MRS=P_1/P_2$, the optimal quantities X_1, X_2 are determined in the usual way as coordinates of the tangential point of budget constraint and indifference map then the optimal partitioning of consumption expenditures ρ_{E1}, ρ_{E2} is also determined. This implies that any configuration of expenditure ratios can be formalized as a consumer optimum.

A straightforward result materializes as another limiting case if the labor inputs of the two firms stand in the same proportion as the expenditures for both products:

$$\frac{P_1}{P_2} = \frac{R_2}{R_1} \quad \text{if} \quad \frac{L_1}{L_2} = \frac{C_1}{C_2} \quad \text{and if} \quad \rho_{X1} = \rho_{X2} = 1 \quad |t \quad (10)$$

If labor input is allocated according to the consumers' preferences, which are revealed by their expenditures, then relative prices are inversely proportional to the productivities in the two lines of production. Budget balancing is not required. Neither are speculations about the shape of a hypothetical production function required. The productivities in period t are measurable. We refer to this configuration as the *competitive structure*. The purely deductive result coincides with 'a doctrine of the utmost importance in political economy' (Ricardo, 1981, p. 13), according to which 'it is natural that what is usually the produce of two days or two hours labour, should be worth double of what is usually the produce of one day's or one hour's labour.' (Smith, 2008, p 45). There is an alternative formulation of eq. (10) that in combination with (2) formally embodies Adam Smith's proposition (Robinson, 1981, pp. 30, 41):

$$\frac{P_1}{P_2} = \frac{L_1^*}{L_2^*} \quad \text{with} \quad L_1^* = \frac{L_1}{O_1} = \frac{1}{R_1} \quad |t \quad (11)$$

The structural axiom set implies as a limiting case that relative prices are equal to the ratio of labor inputs per unit of the respective output (cf. Niehans, 1994, p. 89; Dmitriev, 1986, p. 81). In addition it implies the refutation of Jevons's sweeping critique of the classics. Jevons announced a new era of economic thinking by arguing that authority, i.e. Smith, Ricardo and J. S. Mill, had been on the wrong side and explained the nature of value by 'infinitely small amounts of pleasure and pain' (Jevons, 1911, p. vii). But since the subjective partitioning of consumption expenditures can always be expressed in marginalistic terms there is no contradiction between the 'Jevonian Law of Diminishing Utility' (Dobb, 1973, p. 109) and the classical labour theory of value in its most elementary form.

Let us summarize before we take profit into the picture. As a general structural result which follows directly from the axioms one has for relative prices:

$$\frac{P_1}{P_2} = \frac{X_2 C_1}{X_1 C_2} \quad |t \quad (12)$$

Expressed in ratios the structural value theorem takes these forms:

$$\rho_P = \frac{\rho_{X2} \rho_{E1}}{\rho_{X1} \rho_{E2} \rho_L \rho_R} [\text{i}] = \frac{\rho_{E1}}{\rho_{E2} \rho_L \rho_R} [\text{ii}] = \frac{1}{\rho_R} [\text{iii}] \quad |t \quad (13)$$

Real economies will most probably be found between market clearing [ii] and the competitive structure [iii]. In the competitive structure solely organization/technology stands in relation to relative prices. Neither pleasure and pain, nor demand and supply, nor wages and profits play a role in this state. Whether the budget is balanced or not is a matter of indifference. Obviously it does not follow from the axiom set that this state is 'natural' and that the economy 'gravitates' toward it. This idea was an article of faith among the classics. Open to debate were only the nature of profit and the relation between natural price and the natural rates of wages, profit, and rent (Dobb, 1973, p. 44).

3 Profits and Wages

In the structural axiomatic context the business sector's profit in period t is given with eq. (14) as the difference between the sales revenues – for the economy as a whole identical with consumption expenditures C – and costs – here identical with wage income Y_F^2 :

² Profits from changes in the value of non-financial assets are neglected here. One member of this class is the stock of products which may change with regard to quantity and valuation price if the product market is not cleared in successive periods. This case is excluded by the condition $\rho_X=1$. For the general case profit has to be introduced with the 5th axiom as the sum of financial and non-financial profits.

$$Q_{fi} \equiv C - Y_F \quad |t \quad (14)$$

In explicit form, after the substitution of (3) and (4), this definition is identical with that of the theory of the firm:

$$Q_{fi} \equiv PX - WL \quad |t \quad (15)$$

By applying the first axiom (1) and the definitions (4) and (5) one arrives at:

$$Q_{fi} \equiv C - Y + Y_D \quad \text{or} \quad Q_{fi} \equiv \left(\rho_E - \frac{1}{1 + \rho_D} \right) Y \quad |t \quad (16)$$

To get rid of all absolute magnitudes the profit ratio ρ_Q is defined with eq. (17) and this gives a succinct summary of the structural interrelation of the profit ratio, the expenditure ratio, and the distributed profit ratio for the business sector as a whole:

$$\rho_Q \equiv \frac{Q_{fi}}{Y} \quad \Rightarrow \quad \rho_Q \equiv \rho_E - \frac{1}{1 + \rho_D} \quad |t \quad (17)$$

The profit ratio for the business sector as a whole is positive if the expenditure ratio ρ_E is >1 or the distributed profit ratio ρ_D is >0 , or both. The determinants of profit look essentially different depending on the perspective. For the firm price P , quantity X , wage rate W , and employment L in eq. (15) seem to be all important; under the broader perspective of eq. (16), which is formally equivalent, these variables play no role at all. The profit definition provokes a cognitive dissonance between the micro and the macro view that shall be dealt with at length in section 4.

The first question is how profits are distributed between the two firms. The financial profit for each firm is given by:

$$Q_{fi1} = P_1X_1 - W_1L_1 \quad \text{and} \quad Q_{fi2} = P_2X_2 - W_2L_2 \quad |t \quad (18)$$

Using eq. (10) one gets for relative profits in the competitive structure:

$$\frac{Q_{fi1}}{Q_{fi2}} = \left(\frac{1 - \frac{W_1}{P_1R_1}}{1 - \frac{W_2}{P_1R_1}} \right) \frac{C_1}{C_2} \quad \text{if} \quad \rho_{X1} = \rho_{X2} = 1 \quad |t \quad (19)$$

If the wage rates in both firms are equal the numerical value in the brackets is one and the ratio of profits is equal to the ratio of consumption expenditures for the two products. From the purely formal standpoint it would suffice that the *average* wage rates were equal. It is clear, however, that the differentiation of wage rates within a firm would affect the partitioning of consumption expenditures. To keep things simple, alternative distributions of wage rates within the firms are ruled out.

For the comparison of firms with different size and different absolute profits the respective profit ratios are required. The profit ratio for the business sector as a

whole (17) has been directly derived from the profit definition (14) and is adapted for a single firm as follows:

$$\rho_Q \equiv \frac{Q_{fi}}{Y} \rightarrow \rho_{Q1} \equiv \frac{Q_{fi1}}{W_1 L_1} \quad (20)$$

Using eq. (19) one gets for the relative profits ratios:

$$\frac{\rho_{Q1}}{\rho_{Q2}} = \frac{\frac{1}{W_1} - \frac{1}{P_1 R_1}}{\frac{1}{W_2} - \frac{1}{P_1 R_1}} \quad (21)$$

If the wage rates are equal the profitability of firms is equal. There is, though, no such thing as a law of uniform profitability because there is nothing in the formalism that equalizes the wage rates between firms. For the classics (Mill, 2006a, p. 472) and even more so for Walras (Morishima, 1977, pp. 82-83) profit equalization was self-evident. Of course, a formal proof of overall dynamic profit equalization could not be delivered. The classics simply added the principle of perfect competition to the principle of self-interest (Dmitriev, 1986, pp. 134-135) from where in due time the general equilibrium emerged. This proliferation of more or less plausible behavioral assumptions and the attendant loose verbal reasoning is not exactly what the axiomatic method is all about.

If an equalizing mechanism exists it has to be separately identified and consistently combined with the axiom set. The equality of wage rates and profitability between the two firms is an additional *formal* property of the competitive production structure and not a law-like necessity of the economic system. In fact, it is obviously very improbable that this equality will be realized. This, however, does not affect relative prices as given by eq. (10). For this limiting case therefore follows that the structure of relative prices is independent from the equalization of profit ratios.

When the behavioral equilibrium among firms is defined as the equalization of profit ratios then the behavioral equilibrium and the competitive structure are at odds as long as wage rates are unequal. A reallocation of labor input does not lead to the equalization of profit ratios, only the equalization of wage rate does. Hence, if the firms' behavioral repertoire is restricted to purely quantitative adaption at given prices, the structural conditions ensure prolonged behavioral frustration. Different profit ratios in different lines of production, though, do not jeopardize the functioning of the system as a whole but must be taken as empirical normality. The market economy can exist for an indefinite time without a behavioral equilibrium but not without profits. *That is the sine qua non.* The economy needs either perfect coordination or an adequate margin for erroneous decisions and counterproductive behavior. The safety buffer that ensures a reasonable stability without perfect coordination is provided by profit. The structural precondition of a positive profit ratio for the economy as a whole is given with eq. (17). If the expenditure ratio ρ_E is unity and the distributed profit ratio ρ_D is zero then the profit ratio for the business sector is zero. If wage rates are not equal in this zero-profit economy the profit of

one firm is equal to the loss of the other and this is not a comfortable situation in the longer run. The axiomatic theory of profit is obviously fundamentally different from both Ricardo's 'Corn Theory of Profit' (Dobb, 1973, p. 70) and Mill's abstinence theory (Mill, 2006a, p. 481).

When in the simplest case market clearing and budget balancing is assumed the only subjectively chosen variable is the expenditure ratio for one product. The rest of the system is then determined by the conditions for the competitive structure. If, in addition, the wage rates and the profit ratios in both firms are equal, no improvements are possible, neither for the 'workers' nor for the 'capitalists'. Thus, one has a behavioral and allocative optimum. This configuration is consistent with both the marginalistic theory of consumer optimum and the labour theory of value.

The optimal competitive structure can obviously be generalized for an arbitrary number of firms and products. In marked contrast to the classical approach the structural axiomatic approach asserts that a perfect competitive structure with all desirable properties is possible but not that the economy will attain this state sooner or later. This, though, is not a matter of primary concern. With regard to the proper functioning of the market economy the critical condition is that the expenditure ratio has to be greater than unity (if profit distribution is set aside for the moment) because a zero-profit economy – Walras's 'ni bénéfice ni perte' – is not reproducible with more than one firm.

4 On Profits

It is of utmost importance that profit Q and distributed profit Y_D is clearly distinguished. The latter is a flow of income from the business to the household sector analogous to wage income. By contrast, profit is the difference of flows within the business sector. Profit is not connected to a factor input. So far we have labor input as the sole factor of production and wage income as the corresponding factor remuneration. Since for now the factor capital is nonexistent profit cannot be assigned to it in functional terms. And since profit cannot be counted as factor income (cf. Knight, 2006, p. 308-309, Schumpeter, 2008, p. 153) there is no place for it in the theory of income distribution. This would plainly be a category mistake.

The individual firm is blind to the structural relationship given by eq. (16). On the firm's level profit is therefore subjectively interpreted as a reward for innovation or superior management skills or higher efficiency or toughness on wages or for risk taking or capitalizing on market imperfections or as the result of monopolistic practices. These factors play a role when it comes to the *distribution* of profits between firms and these phenomena become visible when similar firms of an industry are compared. Business does not 'make' profit; it redistributes profit. Because of this it is not wise to take the individual firm as analytical starting-point and then to generalize. The microeconomic approach is prone to the fallacy of composition.

The profit definition entails a cognitive dissonance between micro and macro, but no logical contradiction. In the first place, that is, irrespective of the distribution between individual firms total profit as a factor-independent residual (Ellerman, 1986, pp. 61-65) has nothing to do with price, costs, competition or any other factor that is crucial to the individual firm's management. The existence of total profit is not explicable by the marginal principle.

Under the condition $\rho_E=1$ profit Q must, as a corollary of eq. (16), be equal to distributed profit Y_D . The fundamental difference between the two variables is not an issue in this limiting case. The equality of profit and distributed profit is an implicit feature of equilibrium models and of general equilibrium theory in particular (Patinkin, 1989, p. 329), (Buiter, 1980, pp. 3, 7). These approaches cannot find a counterpart in reality because profit and distributed profit are never equal. Models that are based on the collapsed definition total income \equiv wages + profits (cf. Keynes, 1973, p. 23, Kaldor, 1956, p. 95) are a priori unacceptable because profit and distributed profit is not the same thing.

The classical notion of surplus stands in no relation to profit as determined by (14). Neither is the neoclassical equilibrium condition, profit rate = marginal productivity of capital, applicable in the pure consumption economy because we have profit but no capital. And, since profit and capital cannot be treated like Siamese Twins, as they have by the classics, the tendency of the profit rate to fall is also in need of a thorough revision.

The simplest formula to express the relation between prices and cost of production is:

$$\text{price} \geq \text{cost of production per unit} \quad (22)$$

The classics rightly insisted on the common sense view that production cannot continue for long if the price does not cover the costs and based their value theory on this incontestable fact (Dmitriev, 1986, p. 63). Neither vital necessity nor wishful thinking, though, makes profit to appear and therefore this view cannot explain why profits are in fact positive over a longer time span. When condition (22) is reformulated in structural axiomatic terms and somewhat tightened to exclude zero profits we get condition [i]:

$$[i] \quad \rho_F \equiv \frac{W}{PR} < 1 \quad \Rightarrow \quad [ii] \quad \rho(1 + \rho_D) > 1 \quad \text{if} \quad \rho_X = 1 \quad (23)$$

From the period core (6) then follows condition [ii] which states that the expenditure ratio has to be greater than unity and/or that the distributed profit ratio has to be greater than zero and this condition may be referred to as the life-formula of the pure consumption economy. This formula implies credit growth, at least over some initial periods. For the business sector as a whole to make a profit consumption expenditures C have in the simplest case, i.e. $\rho_D=0$, to be greater than wage income Y_F . So that profit comes into existence in the pure consumption economy

the household sector must run at first a deficit. This in turn makes the inclusion of the financial sector mandatory³.

It needs hardly emphasis that in the investment economy the process of profit generation appears more complex. This does not affect the nature of profit. It simply removes the *formal* necessity that the households have to run a deficit to get the economy going. This is then done by the investing firms.

5 The Rate of Interest

Profit, interest, and rent posed some intricate problems for the labor theory of value (Vianello, 2010). We have dealt with profit above and now include interest. This also gives a clue of how to deal axiomatically with rent which is not considered further here.

To simplify matters it is supposed that all financial transactions are carried out without costs by the central bank. Money then takes the form of current deposits or current overdrafts⁴. The central bank consists of two units, the transaction unit and the banking unit that finances the households which in turn is the precondition for consumption expenditures to be greater than income, i.e. for an expenditure ratio $\rho E > I$. The output of the banking unit consists of the administrative services related to a certain number of one-period loans as given by eq. (35), which is reproduced here:

$$O_2 = R_2 L_2 \quad |t \quad (24)$$

The output's dimension is loans processed per period. With regard to the peculiarities of the banking business it is formally necessary to relate the administrative services to the value of loans. With A , as specified by (49), the average value per loan of the existing average stock of loans AVS_2 (which in turn follows from the cumulated overdrafts) is denoted:

$$O_2 A_2 = (R_2 A_2) L_2 \quad |t \quad (25)$$

Equation (24) is rewritten as:

$$O_2^* = R_2^* L_2 \quad |t \quad (26)$$

The relation between the number of processed loans and the number of loans in the banking unit's books defines the stock-flow ratio ρ_m :

³ When the purchase of long lived consumption goods, e.g. houses, is correctly subsumed under consumption expenditures there arises no problem with regard to collateral for the banking industry and a sound credit expansion may proceed for an indefinite time.

⁴ The cumulated amount of current deposits or overdrafts in period t can be directly derived from the axiom set.

$$\rho_n \equiv \frac{O_2}{n_S} \left[\frac{lpr}{\text{period}} \right] \Rightarrow \rho_n \equiv 1 \left[\frac{1}{\text{period}} \right] \quad \text{if } O_2 = n_S \quad (27)$$

Here we make the simplifying assumption that the whole stock is processed in each period which means that we make no distinction between new lending and the administration of the already existing stock. In this case the ratio ρ_n reduces to one and carries only a dimension.

The households' expenditures (43) consist now also of interest payments to the banking unit. The flow of services bought X is taken to be equal to the output O^* of the banking unit. Under the condition of market clearing the expenditures are equal to the interest payments (see eq. (50)):

$$C_2 = (P_2 \rho_n) AVS_2 = J_2 AVS_2 \quad \text{if } \rho_{X2} = 1 \quad |t \quad (28)$$

For the formal relation between the price P_2 and the rate of interest follows:

$$P_2 \rho_n = J_2 \left[\frac{1}{\text{period}} \right] \quad (29)$$

The rate of interest thereby inherits the role of the price.

If the production structure is competitive then for relative prices holds:

$$\frac{P_1}{P_2} = \frac{R_2^*}{R_1} \quad \text{if } \rho_{X1} = \rho_{X2} = 1 \quad |t \quad (30)$$

Substituting eq. (29) relative prices, here the relation of product price P to the rate of interest J , are finally given by:

$$\frac{P_1}{J_2} = \frac{R_2 A_2}{R_1 \rho_n} \Rightarrow J_2 = \frac{R_1}{R_2} \left(\frac{\rho_n}{A_2^*} \right) \quad \text{if } \rho_{X1} = \rho_{X2} = 1; A_2^* \equiv \frac{A_2}{P_1} \quad |t \quad (31)$$

The loan interest rate J is equal to the ratio of the productivity in the consumption goods producing firm₁ and of the productivity in the banking unit. The latter is weighted with the deflated average loan value. In the competitive structure the interest rate is therefore equal to a relation of real variables. When the average loan value A_2 and the price P_1 always move in lockstep (as they do with perfect indexing of the *nominal value* of the loans), there is no effect on the rate of interest other than productivity changes. If they do not, the rate of interest and the price are positively related

$$J_2 = \left(\frac{R_1 \rho_n}{R_2 A_2} \right) P_1 \quad \text{if } \rho_{X1} = \rho_{X2} = 1 \quad |t \quad (32)$$

and we have to differentiate between a nominal and real rate of interest (a phenomenon we cannot go deeper into here). The loans are produced like any other good and the interest rate therefore truly reflects the production conditions in the

respective industries. The rate of interest fits consistently in the labor theory of value.

The two functions of the central bank, transaction on the one hand (which has been assumed here to be costless) and the processing of one-period loans on the other, are neatly separated. The banking unit is the conceptual nucleus of the commercial banking industry and has eventually to be spun off from the central bank.

The financial profit of the business sector as a whole in period t is derived from the profit definition (15) and eq. (28) as:

$$Q_{fi} = P_1X_1 - W_1L_1 + J_2AVS_2 - W_2L_2 \quad |t \quad (33)$$

In the competitive structure the banking unit's profit ratio is equal to the production firm's profit ratio if the wage rates are equal. The banking unit earns its living like any other firm.

The salient point is that the (loan) rate of interest is not some kind of reward for abstinence or waiting but the price for the services of the banking unit. It is basically not different from any other price that the households pay for any other goods and services.

The classics did not properly discriminate between the rate of interest and the profit rate (Niehans, 1994, p. 97) and maintained that profits are 'an element in Cost of Production, in so far as they are spread over unequal lengths of time' (Mill, 2006a, p. 482). Profits are no costs of production as we have seen in section 2 but interests can be when the business sector finances its operations with loans from the central bank. These interests for the working capital cancel out for the business sector as a whole and determine only the *distribution of profits* between the production firms and the central bank. Mill's notion of profit, although erroneous from the vantage point of the structural axiom set, is realistic given the circumstances of his time when the roles of entrepreneur, owner, and financier fell into one. Nevertheless, he applied only parochial realism which is the defining characteristic of partial analysis. The classical capitalist's roles have to be separated analytically and reconfigured in the general axiomatic context. This has been done; what remains to be done is, of course, the inclusion of 'commodities made by machinery'. Without a full understanding of the elementary consumption economy, though, there is no chance of grasping the complexities of capital accumulation and their implications for the theory of value.

6 Can it be True?

From the differentiated axiom set follows for the competitive structure that the exchange ratio for two products is equal to the inverse productivity ratio (10). Since this statement has been deductively derived it is a theorem. A theorem is different from a law in that it does not make any deterministic claim about real world phenomena. Thus the structural value theorem does not suggest that there

exist market ‘forces’ that make it inevitably true ‘in the long run’ or ‘on the average’. Nevertheless, it may turn out to be applicable to the real world like the Pythagorean Theorem.

First of all it is important to recall that we deal at the moment with a pure consumption economy. That is: no taxes, no foreign trade, no investment goods industry, and no secondary market for durable consumer goods (Ricardo’s rare statues and peculiar wines). Second, the axiomatic value theorem holds but for the product market. In fact the theorem says nothing at all about the labor market, therefore it is a matter of indifference whether the economy is in full employment or not. It does not matter either whether the economy experiences inflation or deflation. In the limiting case of the competitive structure the price relations reflect solely the state of organization/technology.

The conditions for the application of the axiomatic value theorem constitute an elementary consumption economy and are plausible in this restricted domain. They allow for the following conditional prediction. If the allocation of the labor input between firms reflects the preferences of the consumers, as it ideally should with efficient markets, then the exchange ratios of the products are equal to the respective inverse productivity ratios. If the preconditions are approximately realized then we should observe a relatively stable price structure that reflects the productivity development in different industries⁵. Independently of this we should find that the general relation (13) always holds exactly, that is, within the boundaries of measurement errors. In other words, it holds by virtue of pure deduction. What does that mean?

For a general answer let us briefly return to the Pythagorean Theorem. With a known baseline and two known angles one can calculate the unknown and not directly measurable distance to the moon. In physics a theorem is used as a calculating device (Georgescu-Roegen, 1971, p. 332). The usefulness of theorems is beyond question.

The application of a theorem, however, implicitly introduces a new claim. The first claim is that the Pythagorean Theorem is true₁, i.e. formally correct. By applying it to calculate the distance to the moon it is tacitly assumed that earth and moon are located in Euclidean space which is quite another claim that may or may not be true₂. While true₁ refers to the axioms, true₂ refers to reality. Only when the properties of the space that is formally given with the axioms happen to be those of real space the calculation of the distance will yield the correct result. By innocently applying the Pythagorean Theorem we therefore implicitly make the really strong claim that the Euclidean axioms capture reality. If this happens to be the case, and as far as we know it does in the earth’s vicinity, then true₁ and true₂ amalgamate to true₀. Under the condition that the general structural value theorem is true₀ it can

⁵ “Summarizing [the interrelations for Germany], we may conclude that relative productivity growth is the most important determinant of relative price growth, where causality may run the other way as well . . . , but there is no proportional relation between the variables.” (Rahmeyer, 1988, p. 229)

readily be applied as a calculating device that enables valid inferences from known facts to unknown facts.

7 Summary and Conclusions

Behavioral assumptions, rational or otherwise, are not solid enough to be eligible as first principles of theoretical economics. Hence all endeavors to lay the formal foundation on a new site and at a deeper level actually need no further vindication. The present paper suggests three non-behavioral axioms that comprise ten measurable variables as groundwork for the formal reconstruction of the evolving money economy.

This paper has two parts. In the first, the *logical interdependencies* of the key variables that formally embody the firm, the market, and the income distribution are developed. In the second, the *real world implications* for the theory of value are made explicit.

The analytical priority claim of the structural axiomatic approach rests on the simple fact that, since the structure that is given by the axiom set does not adapt to behavior, behavior has to adapt to structure. If behavioral and structural logic are at odds behavioral logic is conducive to frustrated plans and expectations. That is the normal state of economic affairs.

The main results of the axiomatic inquiry are:

- Although Mill propagated the axiomatic method, he actually neither formalized the fundamental behavioral principle nor the theory of value. Hence Mill offers a starting point for both behavioral and structural axiomatization.
- From the differentiated structural axiom set follows the general value theorem which is independent of behavioral hypotheses.
- The competitive production structure as a limiting case of the value theorem is characterized by an allocation of total working hours in exact proportion to the assignment of consumption expenditures to different products and epitomizes the consumers' optimum.
- Given a competitive structure, relative prices are equal to the inverse ratio of productivities. This configuration is consistent with both the marginalist theory of the consumer optimum and the classical labour theory of value.
- Under the additional condition that the wage rates are equal between firms the profit ratios are equal, too.
- Profit is not attributable to capital in the pure consumption economy. Profit is a factor independent residual that is determined by the expenditure ratio and the distributed profit ratio.

- In the structural axiomatic context the (loan) rate of interest is not some kind of reward for abstinence or waiting but the price for the loan processing services of the banking system.
- Profit is no part of the costs of production as Mill maintained. The profit ratio is qualitatively different from the rate of interest.

The general structural axiomatic approach retroactively provides Mill's missing axioms and fits the classical approach consistently into a much broader context.

Appendix

Differentiation of the axiom set (1) to (3) for period t :

$$Y = W_1L_1 + D_1N_1 + W_2L_2 + D_2N_2 \quad (34)$$

$$O_1 = R_1L_1 \quad O_2 = R_2L_2 \quad (35)$$

$$C = P_1X_1 + P_2X_2 \quad (36)$$

$$Y_{F1} = W_1L_1 \quad Y_{F2} = W_2L_2 \quad (37)$$

$$Y_{D1} = D_1N_1 \quad Y_{D2} = D_2N_2 \quad (38)$$

$$Y_1 = Y_{F1} + Y_{D1} \quad Y_2 = Y_{F2} + Y_{D2} \quad (39)$$

$$Y_F = Y_{F1} + Y_{F2} \quad (40)$$

$$Y_D = Y_{D1} + Y_{D2} \quad (41)$$

$$L = L_1 + L_2 \quad (42)$$

$$C_1 = P_1X_1 \quad C_2 = P_2X_2 \quad (43)$$

$$\rho_{E1} \equiv \frac{C_1}{Y} \quad \rho_{E2} \equiv \frac{C_2}{Y} \quad \rho_E \equiv \frac{C}{Y} \quad \Rightarrow \quad \rho_E \equiv \rho_{E1} + \rho_{E2} \quad (44)$$

$$\rho_{X1} \equiv \frac{X_1}{O_1} \quad \rho_{X2} \equiv \frac{X_2}{O_2} \quad (45)$$

$$\rho_{D1} \equiv \frac{Y_{D1}}{Y_{F1}} \quad \rho_{D2} \equiv \frac{Y_{D2}}{Y_{F2}} \quad \rho_D \equiv \frac{Y_D}{Y_F} \quad (46)$$

$$\rho_{F1} \equiv \frac{W_1}{P_1R_1} \quad \rho_{F2} \equiv \frac{W_2}{P_2R_2} \quad (47)$$

Axioms and definitions are consolidated to the period core for two firms:

$$\frac{\rho_{F1} \rho_{E1} (1 + \rho_{D1})}{\rho_{X1}} + \frac{\rho_{F2} \rho_{E2} (1 + \rho_{D2})}{\rho_{X2}} = 1 \quad (48)$$

Definition and Derivation in section 5:

$$A_2 \equiv \frac{\text{average value of stock of loans}}{\text{number of loans in stock}} \equiv \frac{AVS_2}{n_S} \left[\frac{\text{€}}{lst} \right] \quad (49)$$

$$C_2 = P_2 X_2 = P_2 O_2^* = P_2 O_2 A_2 = P_2 \rho_n n_S \frac{AVS_2}{n_S} = J_2 AVS_2 \quad \text{if } \rho_{X_2} = 1 \quad (50)$$
