Abstract

The revelation principle has been known in the economics society for decades. In this paper, I will investigate it from a physical viewpoint, i.e., considering the energy consumed in performing a mechanism.

JEL codes: D7

Key words: Revelation principle; Mechanism design; Implementation theory.

1 Introduction

The revelation principle is a fundamental theorem in economics theory. According to the wide-spread textbook given by Mas-Colell, Whinston and Green (Page 884, Line 24 [1]): “*The implication of the revelation principle is ... to identify the set of implementable social choice functions, we need only identify those that are truthfully implementable.*”

So far, the revelation principle has been applied to many disciplines such as auction, contract, the theory of incentives and so on. If we move eyes from economics to physics, a common viewpoint is that the world is a physical world, doing any action requires energy. In this paper, I will investigate the revelation principle from a physical perspective, i.e., studying how much energy is required for agents and the designer in participating a mechanism. Section 2 and 3 are the main parts of this paper, where I give an energy matrix and

discuss it further. Section 4 draws conclusions. Related definitions and proofs are given in Appendix, which are cited from Section 23.B and 23.D [1].

2 An energy matrix

Let us consider a setting with I agents, indexed by $i = 1, \dots, I$ (page 858 [1]). These agents make a collective choice from some set X of possible alternatives. Prior to the choice, each agent i privately observes his type θ_i that determines his preferences. The set of possible types for agent i is denoted as Θ_i . The vector of agents' types $\theta = (\theta_1, \dots, \theta_I)$ is drawn from set $\Theta = \Theta_1 \times \dots \times \Theta_I$ according to probability density $\phi(\cdot)$. Each agent i 's Bernoulli utility function when he is of type θ_i is $u_i(x, \theta_i)$. A mechanism $\Gamma = (S_1, \dots, S_I, g(\cdot))$ is a collection of I sets S_1, \dots, S_I , each S_i containing agent i 's possible actions (or plans of action), and an outcome function $g : S \rightarrow X$, where $S = S_1 \times \dots \times S_I$ (page 883, Line 7 [1]).

At first sight, it looks trivial to discriminate the exact format of agent i 's strategy. Because the two formats of strategies, actions and plans of action, just correspond to the same results in the traditional theory of mechanism design. However, from a physical perspective, an action should be viewed different from a plan of action.

For any agent i , if his strategy $s_i(\cdot)$ is of an action format, I denote by E_a the energy required for agent i to choose it (i.e., performing the action). Otherwise agent i 's strategy $s_i(\cdot)$ is of a message format (i.e., a plan of action), and I denote by E_m the energy required for agent i to choose it (i.e., selecting the message). Generally speaking, an action is laborious, to carry out it requires more energy; whereas a plan of action is a oral message, to select it requires less energy. This is consistent to the common sense in the real world. Therefore, it is natural to assume $E_a > E_m$. Note the private type of agent i can also be represented as a message, because agent i can announce it to the designer. In addition, I define by E_{send} and E_g the energy consumed in sending out a message and performing the outcome function $g(\cdot)$ respectively.

Consider the indirect mechanism $\Gamma = (S_1, \dots, S_I, g(\cdot))$ that implements the social choice function $f(\cdot)$ in Bayesian Nash equilibrium, and the direct revelation mechanism $\Gamma_{direct} = (\Theta_1, \dots, \Theta_I, h(\cdot))$, where $h(\theta) \equiv g(s^*(\theta))$, $\forall \theta \in \Theta$. Then the revelation principle shows $h(\cdot) = f(\cdot)$, i.e., $f(\cdot)$ is truthfully implementable in Bayesian Nash equilibrium. Let us consider two different cases:

Case 1: Γ is oral, in which each agent i 's strategy is of a message format (i.e., a plan of action).

1) Performing Γ : Given any $\theta \in \Theta$, each agent i selects the strategy $s_i^*(\theta_i)$ and

send it to the designer. Hence, the energy consumed by I agents is $I \cdot (E_m + E_{send})$. The designer receives I messages and perform the outcome function $g(\cdot)$. Hence, the energy consumed by the designer is E_g .

2) Performing Γ_{direct} : Given any $\theta \in \Theta$, each agent i announces a type as a message to the designer. Hence, the energy consumed by I agents is $I \cdot E_{send}$. The designer receives I messages and perform the outcome function $h(\cdot)$. Hence, the energy consumed by the designer is $I \cdot E_m + E_g$.

Case 2: Γ is laborious, in which each agent i 's strategy is of an action format.

1) Performing Γ : Given any $\theta \in \Theta$, each agent i performs his action $s_i^*(\theta_i)$. Hence, the energy consumed by I agents is $I \cdot E_a$. The designer perform the outcome function $g(\cdot)$. Hence, the energy consumed by the designer is E_g .

2) Performing Γ_{direct} : Given any $\theta \in \Theta$, each agent i announces a type as a message to the designer. Hence, the energy consumed by I agents is $I \cdot E_{send}$. The designer receives I messages and perform the outcome function $h(\cdot)$. Hence, the energy consumed by the designer is $I \cdot E_a + E_g$.

Table 1: The energy matrix of I agents and the designer. The first entry denotes the energy of I agents, and the second stands for the energy of the designer.

Mechanism \ Strategy format	Γ	Γ_{direct}
Oral (a message)	$[I \cdot (E_m + E_{send}), E_g]$	$[I \cdot E_{send}, I \cdot E_m + E_g]$
Laborious (an action)	$[I \cdot E_a, E_g]$	$[I \cdot E_{send}, I \cdot E_a + E_g]$

Generally speaking, E_m , E_g and E_{send} can be neglected. Then Table 1 is reduced to Table 2:

Table 2: The simplified energy matrix of I agents and the designer.

Mechanism \ Strategy format	Γ	Γ_{direct}
Oral (a message)	$[0, 0]$	$[0, 0]$
Laborious (an action)	$[I \cdot E_a, 0]$	$[0, I \cdot E_a]$

In terms of computer science, when agents' strategies are actions instead of plans of action, the complexity of the energy consumed by the designer in Γ_{direct} is $\mathcal{O}(I)$, which cannot be neglected. Therefore, in order to make the direct revelation mechanism Γ_{direct} work, an energy condition should be added: *The designer possesses enough energy, at least the sum of energy that all agents would consume when they participate the original indirect mechanism Γ .*

3 Discussion

In the 1930s, there is a “socialist planning” controversy of historical importance. According to Page 15, Line 2 [2], *“To calculate efficiency prices by solving the general equilibrium equations, we must gather information about technology, primary and intermediate resources, and consumers’ preferences, which are widely dispersed and privately owned by numerous economic agents. Given the nature and complexity of this privately held information, it would be prohibitively difficult, if not logically impossible, to motivate numerous private agents to comply with the request from the central planning board and submit this information faithfully for the purpose of computing efficiency prices.”*

Besides this difficulty, there exists another problem for the designer: In a direct mechanism Γ_{direct} , does the designer possess enough energy to carry out all actions that would be done by agents in the original indirect mechanism Γ ? (Generally speaking, there are many factors that may be relevant to agents’ actions, e.g., skill, energy, quality etc. For simplicity, here I only consider one indispensable factor, i.e., the energy required to carry out an action.)

According to Page 378, the 9th line to the last [3], “... the mechanism designer is always at an informational disadvantage with respect to the agents, who, as a collective entity, know more about the true environment that does the designer”. Based on this idea, it looks somewhat “unreasonable” to assume that the designer is always at an energy advantage with respect to the agents, i.e., the designer possesses enough energy that can cover the sum of all agents. However, the energy problem is totally neglected in the theory of mechanism design.

As shown before, the energy condition is very weak when the strategy of each agent i is of a message format. But, when the strategy of each agent i is of an action format, the energy condition may be restrictive. The designer cannot take it for granted that he is always able to carry out all actions on behalf of all agents. When the power of the designer is restricted such that the energy condition does not hold, the revelation principle will no longer hold.

4 Conclusion

In this paper, I propose that if an indirect mechanism is oral (i.e., the strategy of each agent is of a message format), then there is no problem in the classical revelation principle. However, if an indirect mechanism is laborious (i.e., the strategy of each agent is of an action format), then an energy condition should be added to make the revelation principle hold in the real world.

Appendix: Definitions in Section 23.B and 23.D [1]

Definition 23.B.1: A social choice function is a function $f : \Theta_1 \times \cdots \times \Theta_I \rightarrow X$ that, for each possible profile of the agents' types $(\theta_1, \cdots, \theta_I)$, assigns a collective choice $f(\theta_1, \cdots, \theta_I) \in X$.

Definition 23.B.3: A mechanism $\Gamma = (S_1, \cdots, S_I, g(\cdot))$ is a collection of I strategy sets S_1, \cdots, S_I and an outcome function $g : S_1 \times \cdots \times S_I \rightarrow X$.

Definition 23.B.5: A direct revelation mechanism is a mechanism in which $S_i = \Theta_i$ for all i and $g(\theta) = f(\theta)$ for all $\theta \in \Theta_1 \times \cdots \times \Theta_I$.

Definition 23.D.1: The strategy profile $s^*(\cdot) = (s_1^*(\cdot), \cdots, s_I^*(\cdot))$ is a *Bayesian Nash equilibrium* of mechanism $\Gamma = (S_1, \cdots, S_I, g(\cdot))$ if, for all i and all $\theta_i \in \Theta_i$,

$$E_{\theta_{-i}}[u_i(g(s_i^*(\theta_i), s_{-i}^*(\theta_{-i})), \theta_i) | \theta_i] \geq E_{\theta_{-i}}[u_i(g(\hat{s}_i, s_{-i}^*(\theta_{-i})), \theta_i) | \theta_i]$$

for all $\hat{s}_i \in S_i$.

Definition 23.D.2: The mechanism $\Gamma = (S_1, \cdots, S_I, g(\cdot))$ implements the social choice function $f(\cdot)$ in Bayesian Nash equilibrium if there is a Bayesian Nash equilibrium of Γ , $s^*(\cdot) = (s_1^*(\cdot), \cdots, s_I^*(\cdot))$, such that $g(s^*(\theta)) = f(\theta)$ for all $\theta \in \Theta$.

Definition 23.D.3: The social choice function $f(\cdot)$ is truthfully implementable in Bayesian Nash equilibrium if $s_i^*(\theta_i) = \theta_i$ (for all $\theta_i \in \Theta_i$ and $i = 1, \cdots, I$) is a Bayesian Nash equilibrium of the direct revelation mechanism $\Gamma = (\Theta_1, \cdots, \Theta_I, f(\cdot))$. That is, if for all $i = 1, \cdots, I$ and all $\theta_i \in \Theta_i$,

$$E_{\theta_{-i}}[u_i(f(\theta_i, \theta_{-i}), \theta_i) | \theta_i] \geq E_{\theta_{-i}}[u_i(f(\hat{\theta}_i, \theta_{-i}), \theta_i) | \theta_i], \quad (23.D.1)$$

for all $\hat{\theta}_i \in \Theta_i$.

Proposition 23.D.1 (*The Revelation Principle for Bayesian Nash Equilibrium*) Suppose that there exists a mechanism $\Gamma = (S_1, \cdots, S_I, g(\cdot))$ that implements the social choice function $f(\cdot)$ in Bayesian Nash equilibrium. Then $f(\cdot)$ is truthfully implementable in Bayesian Nash equilibrium.
