Abstract

By using data from all available waves of the IMF Coordinated Portfolio Investment Surveys, we explore the dynamics of the determinants of cross portfolio investments. The main aim of our analysis, however, is to understand whether a diversification motive can also be found, among the various determinants. We find strong evidence that, indeed, the correlation between the idiosyncratic components of gdp growth, as well as the correlation between stock returns between pair of countries, that we consider as proxies for diversification, are relevant to explain bilateral portfolio holdings, when unobserved heterogeneity is properly taken into account, by means of a fixed effect, panel estimation (where the fixed effects refer to pair of countries, rather than countries in isolation). Interestingly, the same results, cannot be retrieved from cross section estimations. It also turns out that the diversification motive is less relevant, if at all, in choosing whether or not to invest in a particular area.

Keywords: Coordinated Portfolio Investment Survey, risk sharing, gravity models **JEL codes:** F210, F150, F410

1 Introduction

The objective of this work is to explore the risk sharing role of cross country portfolio allocations. Applying a gravity model as in Lane and Milesi-Ferretti (2008) on data from Coordinated Portfolio Investment Surveys by the IMF (which reports total bilateral portfolio investment assets), we investigate on whether investment decisions of source countries are inspired, among the others, by risk sharing objectives. It is often claimed that the recent surge in globalization opens up new and large opportunities for international risk sharing. The idea is that under the hypothesis of complete markets (perfect risk sharing) agents should invest in foreign countries with a negatively correlated business cycles, or in those countries whose business cycles differ in volatility¹. That this may or may not have occurred is a largely empirical matter, and evidence is far from unambiguous. Moreover, there are two, equally interesting facets to this matter. On the one hand, if countries were willing to reap all the potential benefits from financial globalization, we would expect a negative reaction of bilateral equity holdings with respect to correlations between partner countries' idiosyncratic components of GDP. In order to diversify risk, agents within a country should invest in partner countries whose idiosyncratic GDP are negatively correlated with national innovations to income, which would provide the investing country with insurance against idiosyncratic risk. Secondly, even if this were the case, it should still be checked whether or not cross-ownership of assets did bring about the desired level of income smoothing. In this work we focus on the first of the two questions, and try to understand whether or not countries invest more in other countries' assets, the less correlated their business cycle is with the partner economy. This empirical question was also dealt with in a recent paper by Lane and Milesi-Ferretti (2008), where the authors analyze cross equity portfolio ownerships in the context of a gravitational model. By inserting in the gravity model such explanatory variables as the correlation in economies' growth rates, stock returns and growth rates and stock returns, they show that bilateral cross country holdings do not seem to be driven by diversification purposes. In order to more thoroughly explore this issue, we extend the seminal work by Lane and Milesi-Ferretti (2008) along several dimensions. On the one hand, we use all the available waves of the Coordinated Portfolio Investment Survey to perform a repeated cross section analysis, in search for time changes in the determinants of cross ownership positions. On the other hand, we use the available data to build a panel dataset, which helps in controlling for individual (i.e. pair of countries) unobserved heterogeneity, which might be not easily accounted for otherwise, and lead to possibly different results. That this is indeed the case will be clearly seen in section 5, where the main empirical findings will be discussed. Moreover, the explanatory variable we use to identify diversification determinants of cross ownership positions is quite original, and comes from the decomposition of GDP growth rates in an idiosyncratic and an aggregate component, by means of a simple regression technique. The correlation in the idiosyncratic components of gdp growth will be used, along with other, more standard,

¹Even though business cycles were perfectly synchronized is still possible to pool risk exploiting the different volatility of the business cycles

variables, to shed light on this issue. The rest of the paper is organized as follows. Section 2 frames our empirical question into the current literature, while section 3 and 4 present the data and some descriptive statistics. Section 5 presents the main empirical findings, while section 6 contains some final comments. The detailed description of the variables used in the empirical analyses is relegated to an Appendix.

2 Literature review

The issue of portfolio equity investments has been dealt with, from a theoretical standpoint, from a number of perspectives: financial market incompleteness, transactional frictions in asset markets, and frictions in goods markets. All of these perspectives have in common the fact that the mutual fund separation theorem does not hold, and that one normally sees a certain amount of home bias in domestic portfolio positions. In addition, all of these theoretical models provide some insight for the construction of empirical models of equity portfolio investments. Previous empirical work has dealt with the geography of investment flows, but always with some specific limits dictated by data availability. In particular, most contributions have studied the investment positions of a single country (most often, the United States), or of very few countries. In general, most such contributions have made use of gravity models, of the kind used in international trade analysis, to analyze foreign direct investments and banking flows. For example, Wei (2000) and Stein and Daude (2007) have analyzed the geography of FDI, while Buch (2002) and Rose and Spiegel (2004) have concentrated on bank lending and borrowing. In all these papers the role of bilateral trade as a driver of investment and the role of bank lending have been singled out. There has also been a number of studies concentrating upon bilateral equity investments, such as Portes and Rey (2005), Ahearne et al. (2004), Dahlquist et al. (2003), Yildrim (2003), mostly dealing with the case of United States, and with the issue of portfolio home bias. A remarkable exception in the literature, and a seminal paper which constitutes the benchmark for our research is the work by Lane and Milesi-Ferretti (2008) (LMF, in the sequel). This work is particularly relevant, as it covers a large number of source and host countries, using data from the Coordinated Portfolio Investment Survey (CPIS), run by the International Monetary Fund. In particular, the authors use data from the second CPIS, relating to 2001, and featuring data from 67 source and 218 host countries. The analysis of LMF departs from earlier contributions in several noticeable ways: by resorting to a very wide pool of source and host countries, it can provide a better identification of the potential determinants of portfolio equity investments; by developing a double fixed effects empirical specification, which consists in adding to the empirical model two sets of country dummies, respectively for source and host countries, which help in isolating the relative contribution of bilateral factors, source country factors and host country factors. In fact, by suitably controlling for source country and host country effects, the role of bilateral factors can be more properly identified. Among the other factors whose relevance was tested in their empirical work, a diversification motive was included, but the corresponding results were inconclusive. Risk sharing and home bias (and consequently portfolio investments) have recently been linked in the papers by Lewis (1999), and by Sorensen et al. (2007). Absence of international portfolio diversification and (international) risk sharing may be closely linked, as agents who diversify their portfolios internationally are more likely to obtain smoother income and consumption. Sorensen et al. (2007) find that home bias decreases while risk sharing increases during the 1990s. They measure risk sharing as the distance of consumption growth from a situation of perfect markets (perfect consumption risk sharing), and provide a measure of risk sharing income. Both these measures show improvements, which would hint at a robust and positive correlation between level of foreign portfolio assets and income risk sharing, and between foreign direct investment (FDI) and consumption risk sharing. This issue is obviously linked to another very "hot" topic in the recent literature: whether or not the surge in financial liberalization that occurred in the last two decades has effectively improved on the risk sharing opportunities available to the economies involved. The economic literature is rather divided on this issue, and the empirical evidence is quite mixed. For example, Giannone and Reichlin (2006) register an increase in risk sharing among European countries from the early 1990s when market integration significantly accelerated. They also warn, however, that estimates on selected subsamples may be affected by the subsample choice itself. Kose et al. (2008) find very weak links between financial globalization and risk sharing, over the period 1960-2004, and for the two subsamples 1960-1986 (pre-globalization) and 1987-2004 (globalization). In particular, they find that if globalization does not seem to have exerted any significant impact on risk sharing for the whole sample of countries and the whole period, it has played a negative impact on risk sharing for emerging economies. However, on the shorter globalization sample, only developed countries seem to have reaped some benefits from financial globalization in term of risk sharing, whereas the subset of emerging economies does not seem to have been affected, at least in a statistically significant way. On the other hand, Kose et al. (2006) noticed that financial openness, as measured by gross capital flows as a ratio to GDP, is associated with an increase in the ratio of consumption volatility to income volatility, contrary to the notions of improved international risk-sharing opportunities through financial integration. Kaminsky et al. (2005) investigate over the relationship of net income flows and GDP, and find that net capital flows are procyclical in most OECD and developing countries, i.e. countries tend to borrow in good times and repay in bad times. On the other hand, Bai and Zhang (2004) conduct a regression analysis (both panel and cross section) dividing their whole sample (1973-1998) in two distinct sub-samples (1973-1985; 1986-1998) and conducting separate tests for 19 developed countries, for 21 developing countries and for the whole set of countries. Their study shows that, although the degree of financial integration doubles from the first to the second sub-period, there is no substantial improvement in international risk sharing. Moreover, they claim that international risk sharing is not sensitive to the increase in financial integration. That the need or possibility for diversification of idiosyncratic risks may also be a determinant for bilateral portfolio positions has surfaced in other recent contributions, but only very few have attempted to perform an empirical verification. An interesting work, in this field, is that by Bracke and Schmitz (2008), trying to understand whether equity portfolio investments play a role in

consumption risk sharing both via net investment income and via capital gains. To do so, they analyze a dataset comprising 35 industrial and emerging market economies. In this paper, as anticipated in the introduction, we intend to take one step forward, to explicitly introduce a proxy for the diversification motive in a gravity model for bilateral portfolio investments.

3 Data

Data on bilateral equity holdings for years 2001 up to 2009 come from several waves of the Coordinated Portfolio Investment Survey (CPIS) by the International Monetary Fund (IMF). For comparative purposes we included 67 source² countries and 218 host countries³ as in Lane and Milesi-Ferretti (2008). Original data are expressed in current US dollars. As we are interested in the real dynamics of cross country holdings (actual purchases or sales of assets over time), and since the overall dynamics in the value of asset holdings may also originate from a different valuation of the same positions (both because of changes in asset prices and in relative exchange rates), we had to compensate for the latter source of changes. Therefore, in order to run bona fide longitudinal analyses, data on equity holdings have been deflated by using a Morgan Stanley Capital International (MSCI) price index (period average, base year 2001). Likewise, the value of equity holdings of each given country has been adjusted to account for exchange rate fluctuations by using an index number of bilateral exchange rate between US dollars and the currency of the host country (base year 2001). Analogously, bilateral trade across countries has been adjusted for exchange rate fluctuations. As a result of all these adjustments, equity values are expressed in 2001 current US dollars, at 2001 stock prices. Covariates have been computed following Lane and Milesi-Ferretti (2008).⁴

4 Descriptive Statistics

In tables 1, 2 and 3 we report percentage shares and the growth rates of bilateral equity asset holdings (unweighted and weighted⁵) aggregating over 6 major areas. Data are, as explained in the previous section, in "constant, 2001, terms" since they are adjusted for exchange rate fluctuations and for valuation effects. Off shore centers have been removed, to avoid distortions. Thus, statistics in table 1, 2 and 3 refer to the dependent variable entering our regression analysis. Over the period 2001-2009 the weight of OECD countries is still dominant, since around 74 percent of the total amount of equity asset holding is due to U.S., UK and Euro Area; however, their role is becoming less important over the

²See appendix A for a complete list of source and host countries included in the analysis.

³Source refers to countries undertaking an investment, i.e. purchasing equities in a foreign country, while hosts refers to countries receiving the investment.

⁴For a detailed description of data see appendix B

⁵By period average shares.

observed period of time. In particular, the U.S. and the Euro Area lost respectively about 5 and 2.5 percent of their shares, while UK lost just 0.9 percent. On the contrary, Japan gained one percentage point, other OECD countries and Emerging markets registered a remarkable increase of their weight of around 4 percent. A quick look at unweighted rates of growth of equity asset holdings reveals how Emerging markets quadrupled their international portfolio size, "other OECD countries" and Japan doubled, whereas U.S., UK and the Euro Area have been growing below the average, increasing their equity assets positions by around 50 percent. If we now look at weighted rates of growth (by the corresponding percentage shares of the total, reported in table 3), about half of the increase in total investment can be attributed to emerging markets and to "other OECD countries". To sum up, total growth of equity asset holdings amounts to 76.2 percent and the increasing role of emerging economies and the attractiveness of U.S. and European markets for these countries become quite evident. Moreover, the persistence of bilateral investment patterns decreased somehow over the whole time horizon in comparison to what detected by Lane and Milesi-Ferretti (2008) between 2001 and 2005.6It seems fair to say that, looking at data, there is some evidence of an ongoing change of the international investment patterns, calling for a further investigation over the entire available time horizon.

5 Empirical findings

This section describes the results for cross-section and panel analyses. Cross section analyses have been conducted, as in Lane and Milesi-Ferretti (2008), controlling for countries' characteristics by the inclusion of "double fixed effects" for source and host countries, whereas our panel analysis includes individual fixed effects for each pair of source-host countries, which is less restrictive and allows controlling for specific "pair" effects. The combination of any two countries, in fact, might be influenced by a fixed factor which is potentially different from the combination of the two individual countries effects. Following Lane and Milesi-Ferretti (2008), the estimated model for cross section analyses is:

$$\log(x_{ij}) = \phi_i + \phi_j + \beta Z_{ij} + \epsilon_{ij} \tag{1}$$

where x_{ij} is the equity investment of country i in country j; Z_{ij} is a vector of covariates; ϕ_i and ϕ_j are dummy variables for source and host countries, respectively. This model includes a dummy variable for each source and each host country, so that the constant is given by the sum of ϕ_i and ϕ_j , capturing individual heterogeneity of countries i and j. The strength and the novelty of this approach is that it allows exploiting the bilateral dimension of the data to take into account nationals' characteristics. However, once we have several cross sections, corresponding to various time periods, the time dimension can also be used, allowing for the inclusion of proper individual fixed effects, where by individuals we mean source-host pairs of countries. The inclusion of "pairs fixed effects" allows to capture

⁶If one regresses, as in Lane and Milesi-Ferretti (2008), the log of equity positions in 2001 on the log of equity positions in 2005, one obtains an elasticity of 0.84, while the same exercise between 2001 and 2009 yields an elasticity of about 0.73.

that heterogeneity which characterizes any bilateral portfolio equity allocations. This is more general than in the cross section estimation, imposing each country's fixed effect to be identical irrespective of the partner country (host or source). In terms of number of dummy variables to be estimated, in the more restrictive model a total of i+j individual dummies is to be estimated, while in the panel estimation $i \cdot j$ individual fixed effects are included. Therefore, for the panel analysis we adopt the following fixed effects model specification:

$$\log(x_{ijt}) = \phi_{ij} + \nu_t + \beta Z_{ijt} + \epsilon_{ijt} \tag{2}$$

where ϕ_{ij} are individual intercepts and ν_t are time fixed effects.

5.1 Cross section analysis

For comparative purposes, the first step of our analysis consists in replicating the empirical evidence offered by Lane and Milesi-Ferretti (2008) for the year 2001 and its extension for the whole available sampling period, i.e. 2002-2009, in order to assess possible changes over time in the determinants of international asset allocation choices of responding countries (results available upon request). The estimation results, presented in tables (5-13) essentially confirm those presented in Lane and Milesi-Ferretti (2008): throughout the years, bilateral trade is the single most important explanatory variable of cross country portfolio holdings, though its relevance is much weakened in the Tobit estimation. Other variables proxying for information asymmetries and socio cultural proximity are more or less significant in explaining portfolio holdings, over the years: the logarithm of distance, of time difference, and various dummies for common language, ex colonial past, for being party in a tax treaty, or in a currency union. The variables used to identify a diversification motive for portfolio cross holdings are often significant, but with the "wrong", positive, sign. Their estimated coefficients seem to indicate that agents hold portfolios in countries which are rather similar, in terms of business cycle dynamics and stock markets. We also introduced some additional explanatory variables. in particular, we replaced the variable expressing the correlation between gdp growths with a different one, containing the correlation among the idiosyncratic components of gdp growth. Details about the computation of this variable can be found in the data appendix. The estimated coefficient of this variable is also positive, and does not bring new elements into the picture. One more explanatory variable is worth mentioning, the overall score of freedom in the host country, produced by The Heritage Foundation⁷. It always enters with a positive and significant coefficient across all estimation periods for the full sample and the OECD set, while it gains importance and significance for emerging economies as we move towards the end of the time horizon (2009, though, seems to be an exception). Tables (13)-(15) give an idea of the variability across years of estimated coefficients of just one particular specification of equation (1), namely the specification reported in columns (1) of tables (4)-(12); a cursory reading of these tables show that, for the whole sample of countries, the coefficients of the most important explanatory variable, bilateral trade, increases in magnitude over the

⁷http://www.heritage.org/

whole sample, though non monotonically. The relevance of the other significant variables, i.e. time difference, common language, colonial past, common legal origin and the overall score of freedom in the host country, significantly varies across periods, but at the end of the time horizon is not very different from what it was at the beginning. As for the OECD countries, the relevance of the bilateral trade has an opposite behavior (i.e. decreases over time). The estimated models for the emerging countries are the ones yielding the less satisfactory results, with many explanatory variables being only occasionally significant.

5.2 Panel analysis

As a first empirical exercise, we pool all our cross-section data in a single dataset, applying the "pair" fixed effect structure of equation (2). The results of this estimation, contained in tables 15-20, confirm the relevance of the variables already included in the single cross sections, but reveal something new, in that one of the variables used to proxy the diversification motive, i.e. the correlation in stock returns, becomes now negatively and strongly significant, at least in the linear specification. The estimation results change even more as we move to a proper panel estimation. As is well known, in the context of panel estimations it is possible to properly assess the relevance of fixed effects, i.e. the impact of factors which are peculiar to the individual observations. In our case each observation concerns a pair (source-host) of countries, and the fixed effect refers to some factor which plays a role for this couple, but not necessarily for each economy in isolation. Therefore, any fixed effect is likely to capture the (possibly stable) effect of variables which are relevant for the interaction of those economies, and which cannot be observed or are difficult to quantify. It is highly plausible that such unaccounted for factors be somehow correlated with our proxies for diversification motives (correlations between stock market returns, or correlation between idiosyncratic components of gdp). This unobserved factors may then have an impact on the sign and significance of the estimated coefficients of the latter, if the former become part of the disturbance term, as is likely to be the case in purely cross sectional estimations. As already hinted at above, simple source and host country effects, which were included in the cross sectional estimations, may not adequately account for such factors. We report in tables (16) panel estimates over the period 2001-2009 for the whole sample and the two subsamples (OECD countries and Emerging economies) according to two different specifications: log levels and growth rates (table (16)). We may immediately observe that, as this specification includes both period and cross section fixed effects, all the variables not (sufficiently) changing over time cannot be included, their effect being somehow summarized in the cross section fixed effects. While the effect of bilateral trade is almost always strong and positive, our original research question receives a more clear cut answer. In almost all model specifications both the correlation between the idiosyncratic components of GDP and the correlation in stock returns turned out to be significantly negative. Interestingly, even in the face of a positive correlation between the two variables, they are both significant, suggesting that the comovements between the idiosyncratic components of GDP are significant even if one controls for the correlation between stock returns in two economies. This is true both for the linear specifications and for the non linear,

Tobit specification (but only for the correlation in the idiosyncratic components of GDP). When we look at the results for the two sub samples, however, the diversification motive is supported by the linear specification, but not by the Tobit model. This suggests that the decision to engage in portfolio investments, and that of investing more or less, might have different determinants relative to the sub samples. In particular, it seems that the former depends more on the closeness and similarity of the pair of economies, although it may well be the case that once the decision to open a position in a country is taken, the investment size may also be determined by diversification motives. This is confirmed by the regression results of the probit models, where the diversification variables, and in particular the correlation in stock returns, has a positive and significant coefficient. The opposite situation we get with the tax treaty variable. The fact that a pair of countries are taking part in a tax treaty appears to be significant in determining the choice of investing, but not to have an impact upon the relative dimension of portfolio investments. Bilateral trade is always positive and highly significant in driving international investment portfolio choices. Finally, the overall level of freedom in the host country is always positively significant, as it used to be in the cross section and pooled cross section estimations.

6 Conclusions

The recent surge in financial globalization opened up many investment opportunities for the countries involved. One possible outcome of this process is an increase in portfolio diversification, if bilateral holdings are also driven by diversification motives. Whether or not this has been the case is the research question addressed in this paper, where we extend the analysis proposed by Lane and Milesi-Ferretti (2008) to all available waves of the IMF Coordinated Investment Portfolio Survey; this question is addressed by means of both cross section and panel methodologies. The main empirical result of our analysis is that, indeed, a diversification motive emerges from the data, which mainly concerns the relative size of portfolio holdings. It also turns out, however, that the decision to open portfolio positions in a country depends more on symmetries, rather than differences, in the two countries' cycles.

7 Appendix A

List of source countries excluding off shore centers:

Argentina, Australia, Austria, Belgium, Brazil, Bulgaria, Canada, Chile, Colombia, Costa Rica, Czech Republic, Denmark, Egypt, Estonia, Finland, France, Germany, Greece, Hong Kong, Hungary, Iceland, Indonesia, Ireland, Israel, Italy, Japan, Kazakhstan, Korea (Republic of), Malaysia, Netherlands, New Zealand, Norway, Panama, Philippines, Poland, Portugal, Romania, Russian Federation, Singapore, Slovak Republic, South Africa, Spain, Sweden, Switzerland, Thailand, Turkey, Ukraine, United Kingdom, United States, Uruguay, Venezuela.

List of host countries excluding off shore centers:

Albania, Algeria, American Samoa, Angola, Argentina, Armenia, Australia, Austria, Azerbaijan, Bangladesh, Belarus, Belgium, Benin, Bhutan, Bolivia, Bosnia and Herzegovina, Botswana, Brazil, Brunei Darussalam, Bulgaria, Burkina Faso, Burundi, Cambodia, Cameroon, Canada, Cape Verde, Central African Republic, Chad, Chile, China, Colombia, Comoros, Congo (Democratic Republic of), Congo (Republic of), Costa Rica, Côte d'Ivoire, Croatia, Czech Republic, Denmark, Djibouti, Dominican Republic, Ecuador, Egypt, El Salvador, Equatorial Guinea, Eritrea, Estonia, Ethiopia, Faroe Islands, Fiji, Finland, France, French Guiana, French Polynesia, French Southern Territories, Gabon, Gambia, Georgia, Germany, Ghana, Greece, Greenland, Guatemala, Guinea, Guinea-Bissau, Guyana, Haiti, Honduras, Hong Kong, Hungary, Iceland, India, Indonesia, Iran, Iraq, Ireland, Israel, Italy, Jamaica, Japan, Jordan, Kazakhstan, Kenya, Kiribati, Korea (Democratic People's Republic of), Korea (Republic of), Kuwait, Kyrgyz Republic, Lao, Latvia, Lesotho, Liberia, Libya, Lithuania, Macedonia, Madagascar, Malawi, Malaysia, Maldives, Mali, Mauritania, Mexico, Micronesia, Moldova, Mongolia, Montserrat, Morocco, Mozambique, Myanmar, Namibia, Nepal, Netherlands, New Caledonia, New Zealand, Nicaragua, Niger, Nigeria, Norway, Oman, Pakistan, Papua New Guinea, Paraguay, Peru, Philippines, Poland, Portugal, Puerto Rico, Qatar, Romania, Russian Federation, Rwanda, San Marino, São Tomè and Principe, Saudi Arabia, Senegal, Sierra Leone, Singapore, Slovak Republic, Slovenia, Solomon Islands, Somalia, South Africa, Spain, Sri Lanka, St. Helena, Sudan, Suriname, Swaziland, Sweden, Switzerland, Syria, Taiwan, Tajikistan, Tanzania, Thailand, Togo, Tonga, Trinidad and Tobago, Tunisia, Turkey, Turkmenistan, Tuvalu, Uganda, Ukraine, United Arab Emirates, United Kingdom, United States, United States Minor Outlying Islands, Uruguay, Uzbekistan, Vatican City State, Venezuela, Vietnam, Virgin Islands (United States), Wallis and Futuna Islands, West Bank and Gaza Strip, Yemen, Zambia, Zimbabwe.

8 Appendix B

Bilateral portfolio equity holdings:

millions of U.S. dollar of portfolio equity holdings issued by host countries and held by source country. Source 2001-2009 Coordinated Portfolio Investment Survey.

Bilateral trade:

five-year backward looking moving average of imports plus exports over the period 2001-2009. Source: United Nations Commodity Trade Statistics Database.

Colony Dummy:

dummy taking the value 1 if source and host country ever had a colonial relationship and zero otherwise. Source Rose and Spiegel (2004).

Common Language:

dummy variable taking value 1 if host and source countries share the same language and zero otherwise. Source: Rose and Spiegel (2004) and Lane and Milesi-Ferretti (2008).

Common Legal Origin:

dummy variable taking the value 1 if the source and and host countries have a legal system with a common origin (common law, French, German or Scandinavian) and 0 otherwise. Source: La Porta *et al.* (2005) and Lane and Milesi-Ferretti (2008).

Correlation between growth-stock returns:

twenty one-year backward looking moving average correlation between annual GDP growth rates in the source country and real stock returns in the host country over the period 2001-2009. For the IV estimation the aforementioned backward looking moving average has been restricted to just ten years. Source: authors' calculation based on Morgan Stanley Capital International (Datastream) and World Bank (on-line database World Development Indicators).

Correlation in GDP growth rates:

twenty one-year backward looking moving average correlation between the annual GDP growth rate of source and host countries over the period 2001-2009. For the IV estimation the aforementioned backward looking moving average has been restricted to just ten years. Source: authors' calculation based on World Bank (on-line database: World Development Indicators).

Correlation in idiosyncratic GDP:

twenty one-year backward looking moving average correlation between the annual idiosyncratic GDP growth rate of source and host countries over the period 2001-2009. For the IV estimation the aforementioned backward looking moving average has been restricted to just ten years. The idiosyncratic component of GDP growth is computed as the estimated residuals of the following regression $\Delta \log(GDP_{it}) = \beta \Delta \log(GDP_{at}) + \epsilon_{it}$. Where $\Delta \log(GDP_{it})$ is the country i GDP rate of growth and $\Delta \log(GDP_{at})$ represents the average rate of growth of the reference group (in our case: all countries; OECD countries and Emerging Markets). The GDP growth rate of a given country is therefore decomposed in two orthogonal components: in fact, $\Delta \log(GDP_{it}) = \widehat{\beta} \Delta \log(GDP_{at}) + e_{it}$, thus the idiosyncratic GDP growth will be orthogonal to the aggregate (group average) GDP growth by construction: $e_{it} \perp \widehat{\beta} \Delta \log(GDP_{at})$. The more standard practice (e.g. Asdrubali *et al.* (1996)) consists in simply subtracting the group average GDP growth to each country's GDP rate of growth. However, this practice does not guarantee orthogonality between aggregate and idiosyncratic GDP growth and may generate serious omitted variable bias if one of the regressors strongly correlates with the aggregate GDP growth. Moreover the standard decomposition restricts the coefficient attached to aggregate GDP to be equal to 1, while the empirical evidence contradicts this assumption.

Correlation in stock returns:

eleven-year backward looking moving average correlation between the monthly stock market returns of the host and source country, expressed in U.S. dollars over the period 2001-2009. For the IV estimation the aforementioned backward looking moving average has been restricted to just five years. Source: authors' calculations based on returns data from Morgan Stanley Capital International (Datastream).

Currency Union Dummy:

dummy variable taking value 1 if source and host countries are in a currency union and

zero otherwise. Source Lane and Milesi-Ferretti (2008) and Rose and Spiegel (2004)

Log distance:

logarithm of Great Circle distance in miles between the capital cities of source and host country. Source: Rose and Spiegel (2004).

Overall score of freedom in the host country:

overall freedom score ranging from zero to 100 given by the average of ten component scores: business freedom; trade freedom; fiscal freedom; Government spending; monetary freedom; investment freedom; financial freedom; property rights; freedom from corruption; labour freedom. All 10 components are weighted equally. Source The Heritage Foundation (http://www.heritage.org/)

Tax Treaty:

dummy variable taking value 1 if source and host countries enacted a double taxation agreement prior to 1999. Agreements considered are: Capital, Income and Capital, Income and Inheritance. Double taxation agreements on Air, Land and Sea Transport have been excluded. Source: Authors' elaborations on DTT (Double Taxation Treaties) database from www.unctad.org.

Time Difference:

absolute value of of time difference between host and source country (from 1 to 12). Source: Lane and Milesi-Ferretti (2008) and Rose and Spiegel (2004)
