Abstract

In this paper, the asymmetric and nonlinear effects of the real exchange rate shocks on different export-oriented businesses, i.e. Petrochemical, Basic Metal, and Mining industries stock indexes, in Tehran Stock Exchange is examined. From the policymakers' perspective, this idea is theoretically interpreted as a "fear of appreciation" hypothesis that refers to the intervention of central banks in foreign exchange markets to restrict currency appreciation rather than depreciation to defend export competitiveness. To this aim, in addition to the main variables, the monthly time series data of the control variables, i.e. inflation, OPEC oil price, and international sanctions, from 2012:01 to 2020:01 are used. Our findings based on the NARDL approach illustrate that not only have exchange rate shocks significant effects on different stock indexes, but these relationships are asymmetric and nonlinear. Moreover, the results have confirmed the fear of depreciations hypothesis in the export-oriented industries, that means the central bank of Iran tends to pursue the "leaning-against-the-depreciation-wind" policy rather than "leaning-against-the-appreciation-wind" one.

Key Words: Exchange Rate Shocks, Export-Oriented Industries, fear of depreciation, NARDL Model.

JEL Classification: C58, F31, E44, G32.

1. Introduction

Exchange rate shock and its significant impacts on various indicators of an economy is not, generally, an emerging phenomenon in the economic literature, and there are a variety of examples in the global economy ([Erdoğan et al., 2020](#); [Chen & Lin,](#)

2019; Ho & Huang, 2015). In the case of Iran and, more specifically, after the Islamic Republic Revolution of 1979 until mid-2020, the foreign exchange rate, i.e. the United States Dollar or USD, has experienced extraordinary increases, around two thousand and five hundred times¹(See the Statistical Centre of Iran). This dramatic increase has not occurred through a constant or uniform trend. To be more precise, it has taken place over different unpredicted shocks and high volatile periods. On this basis, the issue that has always attracted particular attention in the realms of macroeconomic policy debates and also business analysis has not been the growth of the exchange rate, but the sudden and unexpected rise in this index. A phenomenon sometimes is called "exchange rate shock" in economic literature (Babajani Baboli et al., 2018). Based on this stylized fact, the primary concern of this paper includes analyzing the impacts of exchange rate shocks on different export-oriented businesses in Tehran stock Exchange, TSE².

To illustrate the crucial role of the stock market in developing countries like Iran, it should be noted that stock market, generally, is one of the essential markets that play a significant role in establishing and maintain the long-run and stable equilibrium in an economy. To be more precise, as a subsector of the financial market, share markets can lead the economy to more capital formation and GDP growth through raising capitals and channelizing the investments into various private or governmental projects or business plans, redistributing of total income and wealth, improving corporate governance³(Erdoğan et al., 2020; Heidari et al., 2019).

Depending on nature, economic infrastructure and strength, production capacity, and the ratio of trade growth to GDP growth, the role of the stock market in an economy depends on several factors and the reaction of market agents to different exogenous shocks that threaten their profitability. In line with this, as empirical studies related to the economy of Iran demonstrate, the most significant threats in this stock market can be classified into two groups: (i) global risks include international sanctions, oil price shocks, and exchange rate fluctuations; (ii) domestic risks like significant movements in the indicators of competitive and alternative financial markets, economic growth, and inflation (Heidari et al., 2019; Haeri Nasab & Sohaili, 2019; Kordlouie et al., 2018). As it is clear from the real evidence of Iran's economy (especially after 2012, 2018, and 2020 rapid decline in Iranian Rial) and also based

¹ From 80 Rial, IRR, up to approximately 200000 IRR

² www.amar.org.ir

³ The main stock market in Iran.

⁴ Through enhancing managerial efficiency and standards to catch the eyes of shareholders

on the results of [Heidari et al., 2019](#); [Zamanian et al., 2017](#); [Jahangiri & Hoseini Ebrahimabad, 2017](#) studies, among all these effective factors, the role of exchange rate shocks seems to be more decisive, especially in recent decades.

Relying on the arguments of [Zarei, 2020](#); [Babajani Baboli et al., 2018](#), and [Zamanian et al., 2017](#), the crucial effects of exchange rate shocks on the stock market can be supported from two assorted views, theoretically and empirically. In this regard, in these two types of research, why does exchange rate shocks play an undeniable role in the spread of instability in the economy of Iran has been addressed. They, moreover, unanimously emphasize that the primary sources of instability and imbalance in the single-product economy of Iran come from a vicious cycle. Regardless of Iran's foreign exchange market's fundamental problems like lack of the central bank independence, the exchange rate misalignment and the existence of multiple exchange rate systems' ([Zarei, 2020](#)), the roots of this vicious cycle stem, on the one hand, from the remarkable reliance of government budget and supplyside of foreign exchange market to the income comes from oil exports; from the volatile nature of the oil market. Consequently, the increased inflation lead to a considerable decrease in the power purchasing parity of domestic currency or a noteworthy enhancement in the foreign exchange rate; again, the increased exchange rate would raise inflation. This cycle will continue with decreasing magnitude of effects. In response, central bank of Iran has adopted a managed floating exchange rate regime to control the ramifications of such a vicious cycle, manage the significant pass-through from exchange rates into inflation, prevent imbalances and inefficiencies in the financial markets, and keep the exchange rate on a long-term equilibrium path. This policy, which known as a "leaning-againstthe-wind" policy, is a type of intervention in the exchange market that implements through selling home currency during the period of appreciation and, conversely, buying the domestic currency while it is depreciating ([Chen & Lin, 2019](#)). Under such circumstances, the responses of various sectors of an economy to exchange rate appreciations and depreciation would be unequal and asymmetric. As a result, statistically investigating of various

¹ That exacerbate the instability in different sectors of the economy.

² Generally, exchange rate appreciation, as a relative export advantage, may lead to a significant economic growth. However, due to reasons like (i) the small share of the non-oil economy; conversely, the significant dependence of Iran's single-product economy on oil exports, (ii) weak infrastructure and lack of suitable platforms to increase Gross Domestic Products, and most importantly, (iii) the existence of international sanctions, exchange rate appreciation cannot necessarily lead to increased exports and the strengthening of the domestic currency, and in some cases, it can even exacerbate the situation and raise the exchange rate again.

industries' reactions to different types of exchange rate shocks is the primary concern of this study. Hence, the main hypotheses of this paper are:

Hypothesis 1: Various export-oriented industries in the Tehran stock market produce an asymmetrical and different reaction to exchange rate appreciations and depreciation.

Hypothesis 2: The effects of real exchange rate shocks on export-oriented businesses follows a nonlinear and asymmetric behavior.

Accordingly, through these hypotheses, we can formally test the idea of whether export-oriented companies in Iran response asymmetrically to exchange rate appreciation and depreciation. In other words, we are going to test the "fear of appreciation" hypothesis in the behavior of export-oriented businesses in the TSE.

To be more precise, the rationale behind this hypothesis is that since central banks, generally, tend to intervene in the foreign exchange market to defend competition in the export-oriented businesses, they usually try to limit exchange rate appreciations rather than depreciation (Zamanian et al., 2017). It is essential to say that, to measure the exchange rate appreciation and depreciation, the exchange rate shocks will be decomposed into the negative and positive components, respectively (See Adeniyi & Kumeka, 2019; Chen & Lin, 2019; Komijani et al., 2013). Therefore, by achieving the time series data of exchange rate appreciation and depreciation, it would be possible to test whether the effects of exchange rate appreciations on the export-oriented businesses (the fear of appreciation hypothesis) is statistically significant.

Simultaneously, we can examine whether the mentioned relationship follows a nonlinear and asymmetric behavior.

Ultimately, in this study, the asymmetric and nonlinear effects of exchange rate shocks on some selected export-oriented businesses in the TSE (which are petrochemical, metal, and Mine stock index) examines. To this aim, in addition to using a NARDL model, which can analyze the asymmetrical relationship between different variables, the monthly standardized logarithmic time series data from 2012:01 to 2020:01 will be used. The data include the selected industries and foreign exchange rate (Dollar to Rials) as the main variables of the study and also some

¹ The same applies for testing the fear of depreciation hypothesis.

² Nonlinear Auto Regressive Distributed Lags: NARDL Model

applicable control variables like inflation, OPEC oil price, and international sanctions imposed on Iran).

2. Theoretical Framework

2.1. Export-Oriented Businesses in the TSE

To address the main concerns of this study, we must, first, determine the answer to these questions that are: what export-oriented industries consider in this study and why? Answering this question requires an overview of the TSE's role and position in the economy of Iran and, also, the industries active in this market.

With more than half a century of experience, Tehran Stock Exchange has been one of the most important stock markets in Iran, while there are also three other types of active stock markets such as Iran's OTC² market known as Iran Fara Bourse (IFB), Iran Mercantile Exchange (IME), and Iran Energy Exchange (IRENEX)³. Various industries are operating in the TSE that the most important of which are: investment industries, petrochemical industries, basic metals industry, mining industries, banks and credit institutions, telecommunications, automobile and parts manufacturing, cement industry, etc. (See Securities and Exchange Organization⁴). Examining the performance, stability, profitability, trading volume and market share of the top 50 companies active in the stock market support the idea that either their field of specialization or investment portfolio components can be categorized in the export-oriented businesses⁵.

The fundamental question here is; what factors have led to the economic prosperity of export-oriented companies in Iran? To answer, it should be noted that the decisive factors cause the expansion of export-oriented businesses are the financial situation, revealed comparative advantages, development strategies, the long-run perspective of the economy in which they act ([Zamanian et al., 2017](#)). Accordingly, the economic authorities of Iran have recently prioritized various programs to reduce the share of oil incomes from the government budget and rely more on non-oil exports. This policy has led the country to choose and pursue the export promotion (vs import substitution) development strategies as its main executive goal. For instance, as stated in Iran's 20-year National Vision (by the end of 2025), achieving first ranked

¹ The rationale behind choosing control variables comes from reasons such as confirmation of theoretical and empirical evidence, stylized facts of Iranian economy, data availability, and the frequency of the available time series data.

² Over-The-Counter

³ In Iran, there is no foreign currency exchange market for transactions, exchanges or investment of foreign currencies in the traditional global form.

⁴ www.en.seo.ir

⁵ Except for some companies that operate entirely domestically.

country in the region by exports and also diversifying and expanding the non-oil exports in the industrial, mining and trade sectors, are the primary missions of the industry, mine, and trade ministry. In line with this, according to the Sixth Five-Year National Development Plan (for 2016–2021), the country's non-oil exports should grow by 21.7 percent annually (should reach \$ 120 billion in 2025). Thus, Iran's strategic policies in its long-run roadmap have led to significant profitability growth in those joint-stock companies that international trade makes up a considerable portion of their activities¹. The common and main features of these companies are (i) most of them are mainly operating (directly or indirectly through investing) in the fields of petrochemical, basic metal, and mining industries in which the Iranian economy has revealed relative advantages; (ii) a significant share of their total income came from international trade. All in all, due to the importance and status of the petrochemical, basic metal, and mining industries, the functional framework of this study concentrates on these export-oriented businesses in the TSE.

2.1.1. Selected Industries: Petrochemical, Metal, and Mining Industries In what follows, a brief overview of the selected export-oriented businesses, i.e. the petrochemical, metal, and mining industries, will respectively be provided to support why these indexes are among the most demanding stocks (even during the sanctions).

A) The Petrochemical Industry Stock Index

As the most critical industries in Iran and Tehran stock market, the petrochemical industry has been an attractive investment destination for many domestic and international investors. Moreover, the foreign exchange earnings of this industry have been the highest among the non-oil exporting industries, especially in recent years. Furthermore, another most interesting point about such industries is that the demand for the products of these companies is so high that despite the international sanctions on Iran's economy, many of them continue to export in various ways (Zarei, 2020). Besides, the petrochemical companies in the TSE have recorded the most positive records like profitability, trading volume, liquidity, demand for purchases, etc. On top of that, due to its vital position in the economy of Iran², this industry has always been able to overcome a significant number of obstacles about financing, taxes, infrastructural, and policies-making problems (Khosrowzadeh et

¹ such as Esfahan's Mobarakeh Steel Company; Persian Gulf Petrochemical Industries Company; National Iranian Copper Industry Company; Ghadir Investment Company; Iran Khodro Automaker company; Esfahan Steel Company; Investment Banks like Saderat, Pasargad, and Mellat; etc.

² That can be proved by the significant number of (over 30%) petrochemical companies among the top 50 companies by early 2020, the total volume of investment in this industry which is far more than each of other competing areas, and the remarkable daily value of traded shares of this industry in comparison with the other traded shares in the TSE.

al., 2020). Therefore, the information about this industry nicely shows the reasons behind the popularity of petrochemical stock index in the TSE.

B) The Basic Metal Industry Stock Index

After the petrochemical industry, the basic metals industry is, generally, in the second place of the top exporting sectors in the country. As reviewing the official news of the TSE show, this average ranking¹ has even saved, approximately, during the first semi-year 2020. Besides, whether it is expected from the companies act in the basic metal industry to have profitability growth, business prosperity, and strong position in the future is a decisive question about the future of this strategic industry in Iran. The convincing reasons that can lead us to expect such a thriving future in that industry include the growing demand for the industry's products in the world, the stable, in average, the trend of high volume transactions in most top stock exchange in the world, and significant profitability of the widely used by-products in international trade, as well as Iran's significant comparative advantage in the production and export of final products and even raw materials such as zinc metal, lead, and copper (Argha et al., 2020).

C) The Mining Industry Stock Index

Remarkable revealed comparative advantage in the Iranian economy together with extensive actual export capacity, have made the mining industry a profitable and stable industry. Precisely, the reasons that helped such companies to become much more lucrative than many other competitors in the TSE are: the diversity of Iran's underground resources, the existence of considerable actual export targets, huge profits and high added value of final manufactured products, high employment rate and export-oriented nature and, finally, becoming an advantage as well as an inflationary shield for shareholders during various exchange rate shocks. More interestingly, as Zolfaghari & Shahabi (2015) claim, Iran's unique capacity for a mass of strategic mineral reserves along with its achievable and feasible export incomes have the potential to be replaced by the total oil revenues in the administration of such a single-product country.

¹ Based on the trading volumes in the TSE

2.2. Asymmetric and Nonlinear Effects of Exchange Rate Shocks

Theoretically, both exchange rate appreciation and depreciation can affect domestic prices, economic growth, stock indexes, and other economic indicators through different channels that are the "marginal cost channel", "inflationary expectations'or markup channel", and "macroeconomic policies channel" (Khosrowzadeh et al.,

2020; Erdoğan et al., 2020; Chen & Lin, 2019). In response to these shocks, economic authorities, private investors, as well as business owners, try to assess and manage the consequences of these shocks. The monetary authorities and governments, on the one hand, make some policies to manage the high level of exchange rates pass-through to domestic inflation, encourage export competitiveness among different firms and businesses, promote economic growth, reduce the likelihood of exchange rate volatility, expand the long-run balance in other markets and consequently the whole economy (Heidari et al., 2019; Jahangiri & Hoseini Ebrahimabad, 2017). Business owners and investors, on the other hand, do not follow public-benefit oriented strategies. They, speculatively, adopt and implement decisions through which they can maximize their profits while the exchange rate is fluctuating (Muller & Verschoor, 2006).

In line with this, almost all recent studies in the effects of exchange rate shocks on different economic indicators can be classified into two groups⁵: (i)

Macroeconomiccenter studies which have concentrated more on the impacts of the shocks on macroeconomic variables like GDP, inflation, unemployment, total private-sector consumption, monetary and fiscal policies, and so forth (See Warsaw, 2020; Dieci & Westerhoff, 2013; Chkili et al., 2012; Fang et al., 2009) (ii) business-oriented researches which have focused on various subsectors or industries of different economies⁶(See Khosrowzadeh et al., 2020; Zolfaghari & Sahabi, 2015).

Moreover, another interesting point is the existence of a common feature or assumption among most of the studies indicates the impacts of exchange rate shocks

¹ Through changing the costs of imported inputs, especially for those firms which provide their inputs from international suppliers.

² With the help of future price adjustments.

³ In other words, by changing the value of imported goods and services due to exchange rate appreciation or depreciation, the domestic suppliers should adapt their prices to maintain their market shares even if they have nothing directly to do with international trade.

⁴ Significant exchange rate movements that culminates in different macroeconomic policies, can change the flow of aggregate supply and demand.

⁵ If the small percentage of interdisciplinary studies is ignored.

⁶ Like banks, agriculture, healthcare, international trade, stock market, etc.

on economic variables (e.g. stock exchange index) are symmetric. For example, if currency appreciation causes a decrease in the stock index, it is assumed that depreciation would have the opposite effects (Bahmani-Oskooee & Saha, 2015). To clarify this issue, Miller and Reuer (1998) argue that, generally, when firms use real options to hedge against fluctuations of the exchange rate, no matter do they active in domestic or international business, their pricing and managerial reactions to the exchange rate appreciation would be different compared to depreciation. This difference in their reactions, support the significance of asymmetric hedging. In the same way, Koutmos and Martin, in 2003, applied and support the idea of asymmetric impacts of exchange rate through measuring exchange rate depreciations and appreciations by decomposing them¹.

Furthermore, the research literature confirms the coexistence of asymmetric relationships and nonlinearity between different economic variables. As the financial theory supports, the reason behind this type of relationship is related to uncertainties caused by some significant high volatile variables like exchange rate. In this regard, while uncertainties spread as a result of exchange rate shocks, the cooperate cash flows will nonlinearly be a function of the exchange rate; the market shares of different firms will be reshaped because of adjusting their price and supply volume; the default risks of companies will change due to the increase in the cost of transactions (Bartram, 2004). Accordingly, studies of Xie et al., 2020; Sikhosana and Aye, 2018; Krapl, 2017; Dieci and Westerhoff, 2013; Fang et al., 2009; Muller and Verschoor, 2006) provide further empirical supports for the existence asymmetric and nonlinearity of the relationship between exchange rate fluctuation and stock price in different case studies. The same will be valid even about the effects of exchange rate volatility on stock index supported by Erdoğan et al., 2020; Warshaw, 2020; Tian and Hamori, 2016; Chkili et al., 2012. They confirm the existence of an asymmetric and nonlinear relationship between exchange rate volatility and stock market index.

2.3. Exchange rate Shocks and Export-Oriented Industries

As one of the influential market-based factors, the exchange rate would be influenced by not only some domestic economic policies but also some international economic and political events (Khosrowzadeh et al., 2020). The unstable nature of this variable

¹ Using the partial sum concept and standard methods in different sectors of the U.S., Japan, Germany, and the U.K., they support the significance of asymmetric exchange rate exposure.

causes many remarkable changes both in macro- and micro-level indexes'. In this respect, most businesses operating in an economy are directly or indirectly affected by movements in the foreign exchange market'. Industries dealing with international trade are among the first directly affected sectors by exchange rate shocks. To be more precise, exchange rate movements can significantly affect the production costs, firms' output, out-of-pocket expenses (like supply costs), the international competitive advantage of all domestic productions, total exports and profits of the companies (Dornbusch and Fischer, 1980); consequently, their shares in the stock markets. The businesses that act completely in domestic markets would indirectly be affected by the fluctuations in the exchange rate due to the likely changes in the imported inputs' costs, inflationary expectations, or profit margin. In this regard, many studies support the effects of exchange rate shocks on the performance of different industries (See Argha et al., 2020; Zarei, 2020; Khosrowzadeh et al., 2020; Heidari et al., 2019; Zolfaghari & Sahabi, 2015). Finally, to achieve the most efficient and significant modelling results, choosing and applying the most appropriate control variables would be valuable and decisive. In harmony with this, despite the remarkable role of exchange rate shocks in explaining the behavior of different export-oriented industries indexes, there are other compelling challenges that have caused significant changes in the production and, subsequently, the export process of such industries (Zolfaghari & Sahabi, 2015; Fang et al., 2009). As reviewing the stylized facts of the economy of Iran demonstrate, the most critical challenges for export-oriented businesses in such a single-product economy would be international sanctions, different economic uncertainties, lack of both domestic and Foreign Direct Investments, i.e. FDI, the inefficiency of the transportation system, cumbersome and inefficient tax system, lack of competition as well as the government management of all these industries. All these challenges can be classified into three groups include (i) fundamental obstacles¹; (ii) policy-making issues²; (iii) market-oriented shocks³. Although investigating the fundamental

¹ Variables like total exports and imports, balance-of-payments, relative competitive advantage, investment, Inflation rate, and GDP as macroeconomic variables, and also input prices, profitability, productivity and the performance of different businesses as micro-level indicators (Babajani Baboli, et al., 2018).

² The extent of this effect depends on several decisive factors, such as: the country's economic power, level of development, manufacturing infrastructure, natural resources and other comparative advantages, financial markets role in channeling investors funds from investors to different corporations, and so forth.

³ Obstacles like inefficient transportation system that is rooted in the economic structure of country.

⁴ Problems such as international sanctions or inflation that represent the results of macroeconomic and political policies can be observed in the changes of such variables. ⁵ Like exchange rate shocks

constraints are not considered in this paper, the main concentration is on one of the major market-oriented concerns in Iran, i.e. exchange rate shocks. In addition to these shocks, some control variables such as the international sanctions, oil price movements, and inflation rate are considered as representative of the policy-making issues.

3. Empirical Results

Based on the vital role of the foreign exchange market in the long-run equilibrium of an economy, like Iran, understanding the extent to which exchange rate's positive and negative shocks affect different sectors of the economy seems essential for both macro and micro decision-makers. Regarding this primary research purpose, together with applying the NARDL model, the monthly standardized logarithmic data of metal stock index (LMTI), mine stock index (LMI), petrochemical stock index (LPCI), the exchange rate (Dollar to Rial), inflation (LINF), OPEC oil price (LOIL), and international sanctions imposed on Iran (S), from 2012:01 to 2020:01, have been used.

In line with this, to demonstrate the features of the data, it should be stated that, firstly, the mentioned data gathered from the official websites of Iran's statistic centre¹, Tehran stock exchange², OPEC³, and the Islamic Republic Iran's central bank⁴. Secondly, as theoretical and experimental evidence indicate, in some cases, the effects of positive and negative exchange rate shocks on various economic variables such as stock market indices are significantly distinctive (or is there a significant difference between "fear of appreciation" and "fear of depreciation"). Consequently, in this paper, the exchange rate data has been decomposed into positive and negative time series, respectively (LEXR⁺) and (LEXR⁻), based on [Ullah et al. \(2020\)](#) survey. Finally, the (S) variable is a dummy one so that the data were one when nuclear sanctions imposed on Iran⁵ and the data were zero when the sanctions were either lifted or suspended.

According to the mentioned data, in the following, various stages will be done to estimate the empirical results. In this regard, a statistically accurate estimation needs

¹ www.amar.org.ir

² www.irbourse.com

³ www.OPEC.org

⁴ www.cbi.ir

⁵ To be more precise, during the investigation period, there were two groups of "One" in dummy variable data to show the periods in which the international sanctions had been imposed. The first one started at 21st march 2012 to 17th December 2015, on which some of these sanctions were lifted. The next one started at 8th may 2017 when the United States announced its withdrawal from the Joint Comprehensive Plan of Action (JCPOA) and prolonged until the end of the study period.

some pre-modelling tests. One of the essential pre-modelling test, especially in using time series data, is a unit root test that helps to eliminate the possibility of spurious regression. In line with this, the ADF stationary test, introduced by [Dicky and Fuller \(1979\)](#), has been exerted on the research variables, as follows:

Table 1: The Unit-Root Tests

	At Level			At First difference		Result
	None	Intercept	Intercept and Trend	None		
LPCI	2.626 (0.998)	-0.909 (0.781)	-1.353 (0.868)	-8.465 (0.000)		I(1)
LMI	-1.182 (0.214)	-2.127 (0.234)	-1.189 (0.907)	-7.511 (0.000)		I(1)
LMTI	-0.815 (0.359)	-2.153 (0.225)	-1.621 (0.777)	-6.574 (0.000)		I(1)
LEXR ⁺	2.186 (0.993)	0.032 (0.958)	-1.212 (0.902)	-4.961 (0.000)		I(1)
LEXR ⁻	4.452 (1.000)	0.998 (0.996)	-0.309 (0.989)	-3.593 (0.000)		I(1)
LINF	0.599 (0.844)	-0.813 (0.811)	-0.107 (0.994)	-2.035 (0.041)		I(1)
LOIL	-1.689 (0.086)	-1.752(0.402)	-2.441 (0.356)	-7.313 (0.000)		I(1)
S	-9.695 (0.000)	-	-	-		I(0)

Table 1 demonstrates that all research variables, except S, which is stationary at level, are first difference integrated, i.e. I(1). Thus, if there is, at least, a long term co-integrated relationship among the non-stationary variables, the concern of spurious regression would be left behind. Therefore, in the table below, the cointegration among three groups of non-stationary variables will be tested by the Johansen- Juelius method, proposed in 1990.

Table 2: The Co-Integration Tests

Variables: LPCI, LEXR ⁺ , LEXR ⁻ , LINF, LOIL & Constant: C and S						
Data Trend	None	None	Linear	Linear	Quadratic	
	No					
		Intercept	Intercept	Intercept	Intercept	
Test Type	Intercept					
	No Trend	No Trend	No Trend	Trend	Trend	

Trace	2	1	1	2	2
Maximum Eigenvalue	1	1	1	1	1
Variables: LMI, LEXR+, LEXR-, LINF, LOIL & Constant: C and S					
Data Trend	None	None	Linear	Linear	Quadratic
	No				
	Intercept Intercept Intercept Intercept				
Test Type	Intercept				
	No Trend	No Trend	No Trend	Trend	Trend
Trace	2	1	1	1	1
Maximum Eigenvalue	1	1	1	1	1
Variables: LMTI, LEXR+, LEXR-, LINF, LOIL & Constant: C and S					
Data Trend	None	None	Linear	Linear	Quadratic
	No				
	Intercept Intercept Intercept Intercept				
Test Type	Intercept				
	No Trend	No Trend	No Trend	Trend	Trend
Trace	2	1	1	1	1
Maximum Eigenvalue	1	1	1	1	1

The results of table 2, based on Trace and Max-Eigenvalue criteria, corroborate that at least one co-integration relationship, are existence among the variables. Therefore, using the NARDL model to evaluate the relationship between the research variables is cogent.

F-Bound		4/01*		5/46*		4/53*

*, **, and ***, respectively, represent 99%, 95%, and 90% significance level.

There are three long-run equations among the different dependent (LPCI, LMI, and MLTI) and independent (LEXR⁺_t, LEXR⁻_t, LINF, and LOIL) variables presented in various columns of table 3. On this basis, results of F-Bound test (as a criterion of the Johansen-Juelius test) demonstrates that the co-integrated (long-run) relationships among each group of variables are statistically certified. In harmony with this, except for the constant variable of LMI, all the coefficients of long-run

NARDL models are significant at the 95%, or more, confidence level. Furthermore, while the coefficients of $LEXR^+$, and $LINF$ in all long-run equations have been positive and significant, the effects of $LEXR^-$, and $LOIL$ have been negative on all three research dependent variables. In addition to the F-bound test, there are other post-modelling (diagnostic) tests that can prove the reliability and significance of such estimated models that CUSUM and CUSUM-Square tests are among the most widely used and reliable. These graphical tests are presented in figures 3 to 8:

FIGURE 3: The NARDL Cusum test Graph of dLPCI

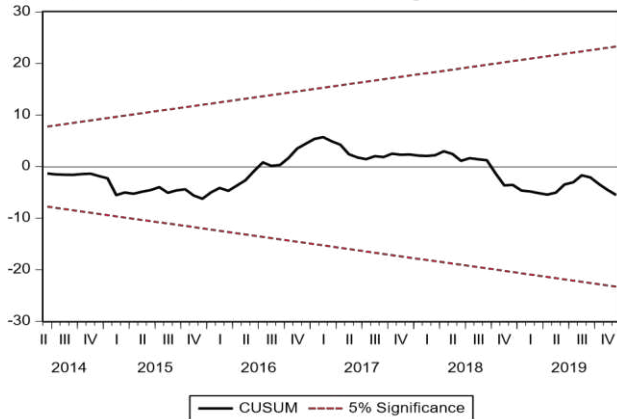

FIGURE 4: The NtARDL Cusum Square test Graph of dLPCI

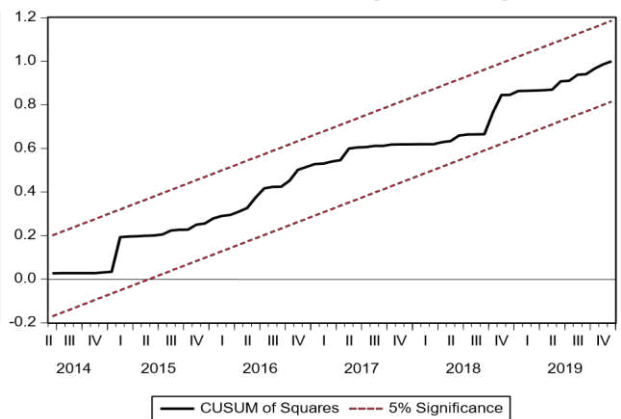

FIGURE 5: The NARDL Cusum test Graph of dLMI

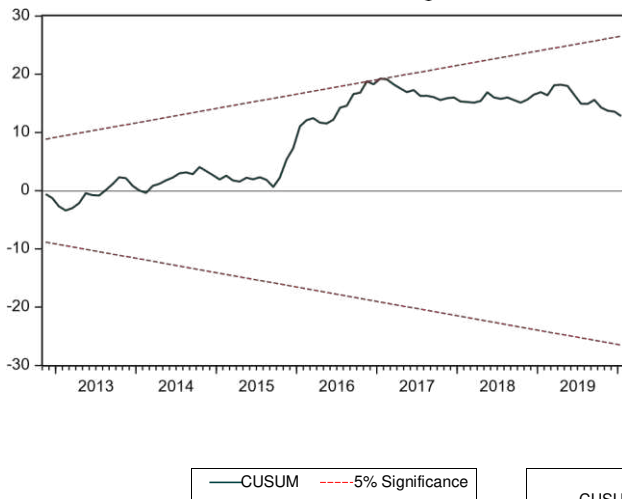

FIGURE 6: The NARDL Cusum Square test Graph of dLMI

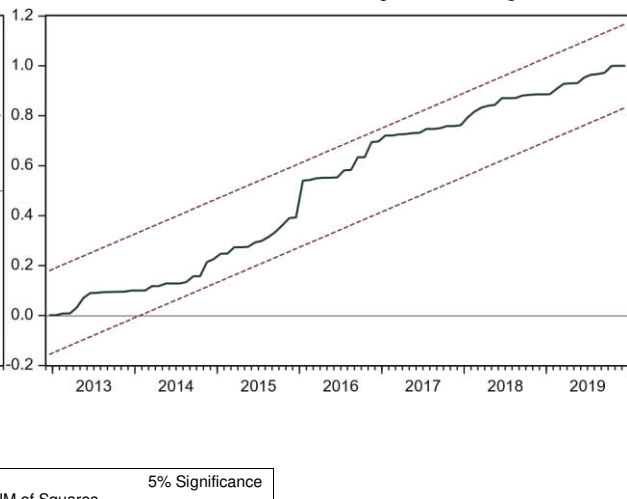

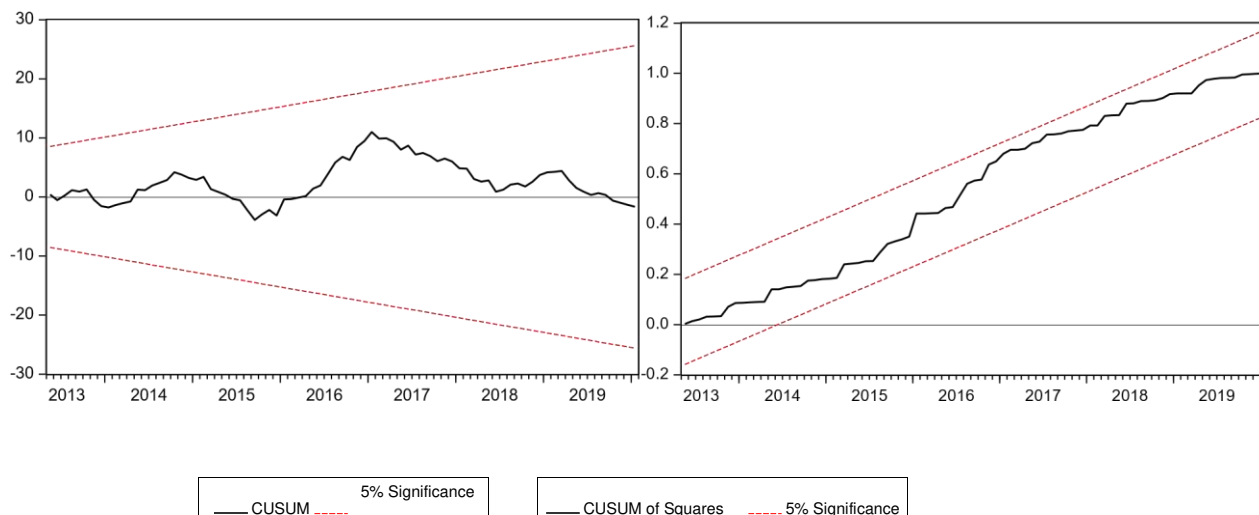

FIGURE 7: The NARDL Cusum test Graph of dLMTI

FIGURE 8: The NARDL Cusum Square test Graph of dLMTI

As can be seen in the above graphs, in each figure, the models' residuals are located in the threshold bounds. Theoretically, this means that the standard errors and squared standard errors of the estimated model are low enough to trust in their results. Therefore, the results of CUSUM and CUSUM Square graphical tests verify the existence of stability in all of three estimated models. On this basis, after calculating the accurate long-run relationships by NARDL model, evaluating the short-run equation are required to figure out the dynamic relationships among these three groups of the research variables.

Table 4: The Short-Run Equations of NARDL Model

Before illustrating the dynamic short-run NARDL model results, it should be noted that both long-run and dynamic short-run (Error Correction model, ECM) estimate as a system modelling. In this study, however, to convey the results more clearly and accurately, we have decided to separate present the long- and short-run results, respectively, in table 3 and 4. This means that diagnostic criteria of NARDL models are pertinent to both tables. In this regard, the adjusted R-squared and F-statistics results confirm the significance and authenticity of three distinctive models. To be more precise, adjusted R-squared for LPCI, LMI, and LMTI are, in order, 96, 93, and 98 percent which means the independent variables of each model could explain approximately more than 90 percent of changes in the dependent variables' behaviors. Besides, the statistics and possibility of the Q (Ljung-Box (test, like Durbin Watson statistics, prove that there is no sign of serial correlations in the residuals of the models. Moreover, the results of the ARCH test show that there is no heteroscedasticity in the residuals of the models. Furthermore, the results confirm that the coefficients of variables are not only significant at 90% confidence level but also consistent with the economic theories as well as the evidence of Iran's stylized

facts. Based on these statistical diagnostic tests, it concludes that the result of the estimated NARDL model is significant and reliable.

In analyzing the coefficients, it should be noted that the C(6) to C(10) coefficients in each of three NARDL estimations are related to Error Correction Terms, ECT, while C(11) to C(24), if exists, are relevant to dynamic short-run equations. In terms of the dLPCI estimated model, three lags of the dependent variable (AR)¹ significantly affect dLPCI, respectively, with coefficients of 0.47, 0.23, 0.16. In addition, the cumulative impacts of dLEXR⁺ and dLEXR⁻ are the most effective variables on dLPCI, i.e. 0.77 and -0.48, respectively. In other words, if the exchange rate increases by one percent, the dLPCI would be augmented 0.77 percent and, similarly, if exchange rate decrease one percent, the dLPCI would be fell down 0.48 percent. Moreover, the effects of dLINF and dLOIL on the dLPCI have, successively, been 0.42 and -0.44. Therefore, each period that sanctions last longer, the dLPCI decline by 0.156 unit.

When it comes to the dLMI, the cumulative coefficients of dLEXR⁺ and dLEXR⁻ are 0.53 and -0.78, whereas those of dLINF and dLOIL are 0.35 and -0.36 respectively. In this equation, the two lags of dependent variables are significant and, more interestingly, the sanctions positively affect the dLMI. In other words, prolonging the international sanctions bring about an enhancement by 0.378 in the mine stock index, which is more than such condition in the case of petrochemical stock index. Additionally, considering the dLMTI, the cumulative influences of dLEXR⁺ and dLEXR⁻ are 0.49 and -0.83, while the cumulative effects of dLINF and dLOIL are 0.37 and 0.16 successively. Moreover, there are two significant autoregressive variables in the model and, more interestingly, lasting sanctions leads to an increase in amounts of both dLMTI and dLMI.

Comparing the results of three different estimated NARDL models, the longestlasting coefficient in the dLPCI, dLMI, and dLMTI is, respectively, dLEXR⁺, dLEXR⁻, and dLINF. Besides, the most effective independent variable in the dLPCI, dLMI, and dLMTI is, successively, dLEXR⁺, dLEXR⁻, and dLEXR⁻. Moreover, the dLINF and LOIL have, in order, positive and negative impacts on the independent variables. Besides, international sanctions cause to increase in both dLMI and dLMTI, while it makes a decrease in the dLPCI during the investigation period. Although in the ARDL model, the error correction term estimates as the coefficient of long-run residual's first lag, in the NARDL model, ECT (or m_h) calculates through the separately estimated coefficients². In this regard, in table 5, the formulas for

¹ Auto-Regressive variables

² The ratio of the independent variables first lag coefficient to dependent variable first lag coefficient, in dynamic short-run equation. This way of evaluating the ECT can give more accurate sights to more meticulously analyzing

calculating each ECT and its longevity are presented. More precisely, ECT coefficient which shows the dynamic relationship in the estimated model, indicates if an exogenous shock makes the model lose its long-term equilibrium path, the impact of this shock (i.e. its longevity) will be disappeared or neutralized after how many periods. Based on these concepts, the longevity of any independent shocks

will be measured by dividing one by the ECT coefficient, i.e. $\frac{1}{ECT}$ (Zarei, 2020).

Table 5: Calculating the ECT of NARDL Model

The Dependent Variable	dLPCI		dLMI		dLMTI	
The evaluated Criterion	ECT	Longevity	ECT	Longevity	ECT	Longevity
$m_{h_1} = \sum_{r=0}^h \frac{\partial Y_{t+r}}{\partial LEXR_{t+r}} = -\frac{C(7)}{C(6)}$	-0.3508	2.85	-0.3043	3.29	-0.2389	4.18
$m_{h_2} = \sum_{r=0}^h \frac{\partial Y_{t+r}}{\partial LINF_{t+r}} = -\frac{C(8)}{C(6)}$	-0.2717	3.68	-0.5817	1.72	-0.4721	2.12
$m_{h_3} = \sum_{r=0}^h \frac{\partial Y_{t+r}}{\partial LOIL_{t+r}} = -\frac{C(10)}{C(6)}$	-0.1748	5.72	-0.0841	11.89	-0.0462	21.65

* Y in each column is the first lag of the dependent variable, respectively LPI_{t-1} , LMI_{t-1} , and $LMTI_{t-1}$.

In the table above, if the shock rises from the positive changes in the exchange rate, the amount of ECT can be measured through $\frac{\partial Y_{t+r}}{\partial LEXR_{t+r}}$. The interpretation of this parameter is if a shock from $LEXM^+_{t-1}$ brings about the instability of the long-run relationship; approximately 0.35 of the instability will be eliminated in each period. Thus, after roughly three periods, i.e. months, a new long-run equilibrium will be reached (this concept refers to the longevity of a shock in long-run). Base on this theoretical concept, the positive and negative exchange rate shocks have the shortest longevity among other independent variables. In other words, after the exchange rate shocks, in order, the inflation and oil price shocks are prolonged. This means that, if a shock from the exchange rate leads to a short-run imbalance, it will be eliminated far sooner than an imbalance caused by the inflation and oil price. Indeed, the effects of the exchange rate are, faster, transmitted to the export-oriented stock prices than the impacts of inflation and oil price.

the relationships among variables than the other ECMs, like ECM, ARDL, CECM, TAR, MTAR, and so forth (Zarei, 2020).

¹ From each independent variables

Finally, the Wald test is, usually, the final diagnostic test to statistically evaluate the authenticity of applying NARDL. The Wald test, which is based on Chi-square statistics, examines whether there is any significant difference between two coefficients of a model. In this regard, we will apply this test to assess the existence of an asymmetric relationship between the positive and negative components of the exchange rate¹ on different dependent variables, i.e. LPCI, LMI, and LMTI. To be more precise, there are three separate subsections in each system modelling², which are the long-run, dynamic short-run, and Error Correction models. Therefore, the mentioned Wald test should be applied to the positive and negative components of the exchange rate in each subsection of the NARDL model that is estimated for the LPCI, LMI, and LMTI.

Table 6: Testing the Existence of Asymmetric Relationship

H ₀	Value	Chi-square	Probability	Results
LPCI				
Long-Run				
C(2)-C(3) =0	3.473011	11.18074	0.0004	Rejected
Dynamic Short-Run				
$\sum_{i=0}^{q1} \alpha_i \sum_{k=0}^{q2} \beta_k [C(14) + C(15) + C(16)] - [C(17) + C(18)] = 0$	1.252174	5.923187	0.0084	Rejected
Error Correction Model				
$m_{h\alpha_1} - m_{h\beta_1} = 0$	0.235347	4.027636	0.0265	Rejected
LMI				
Long-Run				
C(2)-C(3) =0	3.774532	12.56703	0.0002	Rejected
Dynamic Short-Run				
$\sum_{i=0}^{q1} \alpha_i \sum_{k=0}^{q2} \beta_k [C(13) + C(14)] - [C(15) + C(16) + C(17)] = 0$	1.510952	5.092847	0.0138	Rejected

¹ This is the only variable asymmetric coefficients of which can be tested by Wald test due to the fact that it has two different components, positive and negative.

² For each dependent variables such as LPCI, LMI, and LMTI.

Error Correction Model				
$m_{h\Delta_1} - m_{h\Delta_1} = 0$	0.278625	6.116542	0.0075	Rejected
LMTI				
Long-Run				
$C(2)-C(3) = 0$	3.251019	9.341260	0.0012	Rejected
Dynamic Short-Run				
$\sum_{i=0}^{q^1} \alpha_i \sum_{k=0}^{q^2} \beta_k [C(13) + C(14)] - C(17) = 0$	0.838543	6.154353	0.0074	Rejected
Error Correction Model				
$m_{h\Delta_1} - m_{h\Delta_1} = 0$	-0.76871	3.741234	0.0317	Rejected

As can be seen in the table above, it has been approved that there are statistically significant asymmetric relationships between positive and negative components of the exchange rate in all the mentioned equations and different time horizons.

4. Conclusions and Implications

A nonlinear asymmetric model, NARDL, has been conducted to analyze the impacts of real exchange rate shocks on three export-oriented businesses (petrochemical, mine, and metal stock indexes), acting on the Tehran Stock Exchange. In this regard, the time series data of inflation, oil price, and international sanctions (as control variables), and the mentioned stock indexes as well as positive and negative components of real exchange rate (as main variables) have been considered in the period from 2012:01 to 2020:01. In line with this, the findings of research are as follows:

First of all, since the direct relationships among the dependent variables and exchange rate components have significantly been proven, the "fear of appreciation" hypothesis as one of the main concerns of this paper is rejected; conversely, the "fear of depreciation" is confirmed. In other words, our result show that central bank of Iran tends to pursue the "leaning-against-the-depreciation-wind" policy rather than "leaning-against-the-appreciation-wind" one. More precisely, when the exchange rate increased, the LPCI, LMI, LMTI have been raised, i.e. the higher exchange rate, the more expensive products in the international arena. The reason behind this issue roots in the type of these three industries. Indeed, these are export-oriented industries

for which exchange rate appreciation gives significant rise to their products demand depreciation.

Secondly, the other research hypothesis, "various export-oriented industries in the Tehran stock market produce an asymmetrical and different reaction to exchange rate appreciations and depreciation", is confirmed in both the long- and short-run horizons. In the different time horizons equations of these three industries, the coefficients of the exchange rate positive and negative components were various. Precisely, the positive effects of exchange rate on petrochemical industries are higher than those of mine and metal industries. In contrast, the negative impacts of the real exchange rate on mine and metal industries are more than that of petrochemical industries. There are some compelling reasons for this phenomenon. Firstly, having less alternative as well as being more applicable in different industries, petrochemical industries have more demand than the two other research dependent variables. Moreover, supply shortage, towards aggregate world demand for petrochemical products, makes them more strategic even than the products of other export-oriented industries.

Thirdly, the final hypothesis, "effects of real exchange rate shocks on export-oriented businesses follows a nonlinear and asymmetric behavior", is accepted. Since the results of whole NARDL model were statistically significant (based on FBound, for the long-run models, and F-Statistics, for dynamic short-run models), the nonlinearity of the relationship among variables have significantly been approved in all research estimated models. Moreover, the asymmetric relationship among dependent variables and two separate components of the exchange rate, in long-run, dynamic short-run and error correction term viewpoints, have been confirmed based on Wald test results. Regarding this, it seems that the "inflationary channel" for the positive effects of exchange rate works more for mine and metal than petrochemical industries. Indeed, when the exchange rate increase, two events would occur in Iran's stock market, (i) exchange rate pass-through via the inflationary channel and (ii) more demand for the export-oriented products due to reducing relative prices. These conditions, along with the low marginal cost of petrochemical, mine and metal products, bring about more profitability in such industries. Thus, through positive investors' expectations, international demand, and inflationary pass-through, an exchange rate appreciation lead to an increase in the three survey dependent variables. However, when an exchange rate decrease has taken place, both the relative and competitive advantages of these three industries would be declined due

¹ Because these three industries have less operative costs (in dollar) like meeting foreign raw materials together with fixed cost (in dollar) that need to be met once like importing technology.

to becoming more expensive than before the exchange rate decrease. Therefore, an exchange rate depreciation gives rise to a reduction in sales and export amounts of all these industries. In this context, the point is that the same amounts of exchange rate appreciation and depreciation make assorted changes in each of petrochemical, mine and metal stock price industries. It means that the LPCI, LMI, and LMTI react asymmetrically to the exchange rate either appreciation or depreciation so that the effects of exchange rate depreciation in mine and metal industries are more than the same impacts of exchange rate appreciations. Nonetheless, in petrochemical industries, the influences of exchange rate appreciations are more than those of exchange rate depreciation. This issue roots in the global scarcity of petrochemical products in comparison with that of mine and metal industries. Such a circumstance brings about more downward sticky-price for petrochemical stock index than the two other sectors.

Related to the exchange rate and stock price relationship, findings of the present study are consistent with the results of [Xie et al. \(2020\)](#); [Warshaw \(2020\)](#); [Sikhosana and Aye \(2018\)](#); [Krapl \(2017\)](#); [Tian and Hamori \(2016\)](#); [Dieci and Westerhoff \(2013\)](#); [Fang et al. \(2009\)](#); [Muller and Verschoor \(2006\)](#); [Bartram \(2004\)](#); [Koutmos and Martin \(2003\)](#); [Miller and Reuer \(1998\)](#).

Ultimately, the other findings of the investigation are pertinent to the effects of the inflation, oil price, and sanction on the Petrochemical, mine, and metal stock indexes. In this regard, the inflation changes directly affect, respectively, the LPCI, LMTI, and LMI in the long- and dynamic short-run horizons. It is axiomatic that an increase in inflation gives rise to the national currency devaluation. Subsequently, a decline in relative prices of exported goods, rising demand for the products, make more profitability and ultimately augment their stock prices. However, the oil price has an indirect relationship with the dependent variables so that the impacts of this control variable on the petrochemical stock index is far more than the others in each time horizons. An enhancement of the oil price has boosted the government's export revenues. As a result, it would increase the foreign currency supply in the domestic markets; consequently, appreciate the national currency value. This way, the relative prices of local products would enhance that can culminate in less export in international scale and, finally, significant reductions in the export-oriented stock prices. Furthermore, during the study period, the international sanctions make an astonishing number of limitations on Iran's export effects of which have been reflected on these three industries by the decline of their stock prices.
