Silver Spoons and Scales of Justice: The Fairness Preference over Unequal Intergenerational Wealth Transfers *

Kelin Lu[†]

June, 2024

Abstract

Intergenerational transfers are both common and markedly unequal. This study conducts a large-scale experiment to explore how Americans and Chinese perceive the fairness of unequal wealth transfers. In the experiment, workers and their parents completed assignments. Workers' payoffs originated from either (1) their own merit or luck or (2) earnings transferred from their parents, which were also earned through the parents' merit or luck. Impartial spectators made real distributive decisions that affected paired workers. Our findings reveal that Americans exhibit a pronounced aversion to intergenerational transfer inequalities compared to self-earned wealth, whereas the Chinese show only a mild aversion. Additionally, Americans demonstrate a preference for intergenerational meritocracy, accepting greater inequalities in transferred wealth when parental earnings result from merit rather than luck—a preference not evident among the Chinese. Further experiments suggest that attitudes toward unequal intergenerational wealth transfers are primarily driven by whether parents possess wealth to transfer, rather than the choice to transfer it.

1 Introduction

Intergenerational transfers, including inter-vivo transfers and inheritances, are prevalent. In the U.S., the annual inheritances and inter vivos transfers averaged approximately \$350 billion (2016 dollars) from 1995 to 2016, equating to the total personal savings recorded during the same period (Feiveson and Sabelhaus, 2018). However, these transfers are highly unequal. Wealthier parents often give substantially more to their adult children than low-income parents, who may lack the means to provide and sometimes even rely on financial support from their children (Bowles and Gintis, 2002)¹. Recent studies have debated the role of intergenerational transfers as a crucial factor contributing to inequality (Piketty, 2011, 2014; Elinder et al., 2018; Boserup et al., 2016; Black et al., 2022).

To what extent do people view it as fair for wealthy parents to transfer significant amounts of wealth to their children? The answer to this question is crucial as it influences the design and public support of related policies, such as inheritance and gift taxes (Starmans et al., 2017; Cappelen et al., 2020). Consequently, the implementation of these redistributive tax policies further impacts the immediate and future dynamics of societal inequality (Nekoei and Seim, 2023). Additionally, perceptions of fairness directly affect individual welfare, potentially reducing effort and investment due to perceived unfairness (Bjørnskov et al., 2013).

Much of the existing literature focuses on fairness preferences over self-earned wealth inequality (see a recent review by Cappelen et al., 2020). This body of work documents a consistent pattern of meritocratic fairness preferences: inequalities arising from merit, such as performance and risk-taking, are seen as more acceptable than those resulting from uncontrollable luck. In this paper, we advance the literature by providing an incentivized experimental measurement of fairness preference over unequal intergenerational wealth transfers.

This paper aims to address two main questions. First, do people have a meritocracy fairness preference within intergenerational transfer? That is, are individuals more accepting of intergenerational inequality when parents have earned

¹ Pew Research Center, January 2024, “Parents, Young Adult Children and the Transition to Adulthood”

their wealth through merit rather than luck? While the existing literature documents a robust pattern of meritocracy fairness view for self-earned wealth, whether this pattern persists in intergenerational inequality is not straightforward. From the older generation’s viewpoint, there may be a strong argument for respecting parents’ merit in wealth generation and their intentional wealth transfers to subsequent generations. In contrast, from the younger generation’s perspective, such unequal transfers originate from the older generation and are largely beyond the children’s control. Consequently, all forms of intergenerational transfers might be perceived similarly, regardless of how the wealth was earned.

Second, and perhaps more importantly, do people view inequality caused by wealthy parents’ transfers as fair as inequality from self-earned wealth? The existing studies on self-earned wealth are silent on this issue. However, anecdotal evidence suggests that people consider it unjustifiable for wealthy parents to continue shaping the economic futures of their descendants through such transfers. For example, [Piketty et al. \(2023\)](#) advocates for higher taxes on inherited wealth than on self-made wealth.

To address our research questions, we conducted a tightly controlled, incentivized experiment.² We recruited college students as “workers” to complete assignments, and one of their parents was also recruited to participate. Both students and parents participated concurrently from separate locations, with communication between them prohibited to ensure the independence of their decisions. We verified familial relationships by requiring parents to provide their child’s college ID number and an official document, which we then cross-checked against the student’s enrollment records. Importantly, we recruited a large and broadly representative sample from both the United States and China, each consisting of over 2,700 participants, termed “spectators.” These spectators were tasked with deciding how to

² Answering these questions using field data presents significant challenges. First, fairness preferences for redistribution are not directly observed in the field. Empirical studies often rely on various proxies, such as support for redistribution policies ([Roth and Wohlfart, 2018](#)), yet factors like efficiency concerns and trust in government also shape support for these policies ([Stantcheva, 2021](#)). More fundamentally, field data often does not capture people’s beliefs about the sources of inequality. Even when such beliefs are identified, isolating them in a *ceteris paribus* analysis is challenging due to confounding factors. For instance, it is commonly believed that individuals receiving large wealth transfers may exhibit lower work effort—a concept known as the *Carnegie Conjecture*.

redistribute initial earnings between two paired “workers.”

The experiments began with four between-subject treatments: the luck treatment (L), the merit treatment (M), the luck-parent treatment (LP), and the merit-parent treatment (MP). The workers in each treatment completed the same assignment under the same incentive. The only difference was that their initial earnings were determined by different rules, which were not disclosed to the workers before or after the assignment.³ In the L and M treatments, paired workers’ initial earnings were independently determined by a random lottery or their performance, yielding 0 or 6 points. In the LP treatment, parents’ earnings were determined by the lottery, with possible earnings of 0 or 15 points. Parents who earned 15 points were asked if they wished to transfer 6 points to their child. Parents were informed that this transfer would determine their child’s final payment, although other factors might also play a role. Parents who earned no points could not make a transfer, and all transfer decisions were anonymous to their children. The MP treatment followed the same setup as LP, except that parents’ earnings were based on their assignment performance.⁴

Spectators were fully informed of the conditions under which the workers and their parents operated. We ensured that all workers, across treatments, were perceived identically by spectators, except for the rules determining their earnings. Given that the initial earnings of the paired workers were determined independently, one pair could have three different initial earning outcomes.⁵ We employed a contingent response method to assess the spectators’ fairness preferences, requiring them to make redistribution decisions among the workers for all possible earning outcomes. Our analysis, however, focuses primarily on scenarios where earning distribution was unequal, with one worker receiving 6 points and the other receiving none.

³ Workers only know their performance might determine their payoff, but other factors might play a role.

⁴ In the L and M treatments, parents’ earnings were also determined by either luck or performance. However, these treatments were designed so that parents’ earnings had no connection to the children’s initial earnings. Appendix Tables A6 and A5 demonstrate that parents’ earnings determination does not influence spectators’ redistribution decisions over children’s self-earned wealth.

⁵ One worker has 6 points, and another has 0 points; both workers have 6 points; or both workers have 0 points.

The LP and MP treatments capture crucial aspects of real-life intergenerational transfers. First, the earnings of the younger generation is directly affected by decisions made by their biological parents, underscoring the significant and binding role of parents compared to other relatives or friends (Rubin and Chung, 2013). Second, parents experience the outcomes of their earned wealth directly rather than solely working for their children as designators. Third, it is the parents' own will to decide whether to further influence the next generation by transferring a portion of their wealth.

We present several key findings. In the U.S. samples, we first confirm the prevailing meritocratic view of fairness, consistent with existing literature. Specifically, Americans were more inclined to accept unequal distributions in the Merit treatment compared to the Luck treatment. Second, evidence supports the notion of intergenerational meritocracy: Americans showed a greater willingness to accept unequal intergenerational transfers when parental earnings were the result of merit (MP treatment) rather than luck (LP treatment). Third, Americans view inequalities stemming from intergenerational transfers as highly unfair. For instance, they are less tolerant of inequality in the MP treatment compared to the M treatment. Similarly, they accept significantly less inequality in the LP treatment compared to the L treatment. In fact, the accepted inequality in the MP treatment is even marginally lower than in the L treatment.

The analysis of perceptions among adults in China yields different insights. First, while the Chinese, like their American counterparts, accept more inequalities that stem from merit rather than luck, the difference in inequality acceptance is notably closer. Second, we found no evidence supporting an intergenerational meritocratic fairness view in China, as the differences in inequality acceptance between MP and LP treatments were negligible. Third, our findings only weakly suggest that unequal intergenerational wealth transfers are viewed as unfair in China. Specifically, while the acceptance level of inequality in the MP treatment is lower than that in the M treatment, the differences are not robustly statistically significant. Moreover, the acceptance levels of inequality in LP treatment are comparable to those in L treatment.

To better understand the treatment effects, we estimated the prevalence of three

fairness views frequently discussed in the literature: libertarian, meritocratic, and egalitarian (e.g., Cappelen et al., 2007, Almås et al., 2010, Cappelen et al., 2013, and Almås et al., 2020). We conduct these estimations in both the self-earned and intergenerational transferred wealth contexts. Our findings indicate that in the U.S., a significant proportion of libertarians in the self-earned context transition into egalitarians in the intergenerational context. In China, a notable fraction of meritocrats in the self-earned context also shift towards egalitarian views in the intergenerational context. Additionally, we explored the treatment effects across various demographic groups, uncovering some heterogeneity within each country.

The inequality observed in the MP and LP treatments stems from two sources: (1) the disparity in parents having wealth available to transfer, and (2) the decision by some “wealthy” parents to transfer earnings while others choose not to. To better understand which sources influence the aversion to unequal intergenerational wealth transfers, we introduced two additional treatments, MPN and LPN, where N stands for “no choice.” These treatments mirror the MP and LP settings, except that the transfer is mandated. Once parents complete their assignments and learn how their payments are determined, they are informed that a portion of their earnings will be automatically transferred to their children. We find that the results from the MPN and LPN treatments are similar to those of the MP and LP treatments. Hence, people’s attitudes toward unequal intergenerational wealth transfers are mainly driven by the fact that some parents have wealth to help their children while others do not.

What psychological mechanism underlies the aversion to inequality resulting from intergenerational wealth transfers, as opposed to self-earned wealth? One potential explanation is the negative perception of intergenerational mobility generated when wealthy parents, already advantaged by their wealth, continue to influence economic outcomes for future generations through these transfers. Alesina et al. (2018) discovered that the perception of low intergenerational mobility heightens support for redistribution in the U.S. and Europe. Another explanation is that individuals aggregate parental and children’s earnings when redistributing transferred wealth to the younger generation. This could imply that people view the tax system for self-earned earnings as fundamentally unfair and seek to rectify this

through more aggressive redistribution in cases of transferred wealth. If this conjecture were accurate, we would expect a greater likelihood of spectators redistributing more than half of the wealth to low-income children in intergenerational contexts (MP, LP, MPN, LPN) compared to self-earned contexts (M and L). However, our data does not support this conjecture.

Related Literature: Our paper contributes to a large and growing body of empirical research on fairness attitudes toward inequality. Fairness as a motivator of behavior is well established within the literature, as extensively reviewed by Cappelen et al. (2020). Much focus has been placed on the conditions under which inequality is perceived as more or less acceptable (Konow, 2000; Cherry et al., 2002; Falk et al., 2003; Alesina and Angeletos, 2005; Cappelen et al., 2007; Almås et al., 2010; Cappelen et al., 2010, 2013; Durante et al., 2014; Mollerstrom et al., 2015; Akbaş et al., 2019; Cassar and Klein, 2019; Almås et al., 2020; Andreoni et al., 2020; Cappelen et al., 2020, 2022c,a; Bortolotti et al., 2023; Cappelen et al., 2023). These studies document that inequalities arising from “personal choice”, such as risk-taking or superior performance, are typically viewed as fairer and more legitimate than those stemming from factors outside individual control, like sheer luck. However, the circumstances where people made their choices might also matter (Bhattacharya and Mollerstrom, 2022; Dong et al., 2022; Andre, 2024). Our research contributes to the fairness literature by examining the extent to which people perceive large wealth transfers from wealthy parents to their children as fair.

Freyer and Günther (2022) and Cohen et al. (2022) investigate how spectators allocate earnings when determined by friends or strangers. Our design has three fundamental differences that are essential for capturing the nuances of intergenerational wealth transfers. First, our setup involves actual parents making decisions, providing a culturally relevant perspective on familial wealth transfers. Second, it allows parents to directly benefit from their earnings rather than work solely for their children’s benefit. Third, parents independently decide whether to transfer a portion of their wealth. In contrast, in the studies by Freyer and Günther (2022) and Cohen et al. (2022), a friend or stranger merely serves as a designator, instructed to transfer all earnings to workers, thereby not experiencing the consequences of their earning generation. This designator setup may lead spectators to equate transferred

wealth with self-earned wealth. Supporting this, findings from these studies show no difference in spectator perceptions between self-earned and designated wealth contexts. However, our results distinctly differentiate perceptions of self-earned versus transferred wealth.⁶

Taken together, the insights from Freyer and Günther (2022) and Cohen et al. (2022) are particularly valuable for understanding scenarios where third parties, such as trust fund managers, public officials, or legal guardians, act as mere designators of someone. We advance the literature by focusing on familial wealth transfers. Such differentiation underscores the diverse contexts in which fairness is evaluated and highlights our study's unique contribution to understanding the dynamics of intergenerational wealth transfers.

Furthermore, our study relates to recent research that examines differences in fairness perceptions between the U.S. and Europe, often focusing on Scandinavian countries, through experiments with large-scale representative samples (Almås et al., 2020; Almas et al., 2021; Bhattacharya and Mollerstrom, 2022). Cappelen et al. (2022b) compare fairness preferences between individuals in China (specifically Shanghai) and Norway. Our research contributes to this body of literature by providing evidence of fairness views between the U.S. and China, the two largest economies globally.

Second, this paper contributes to the extensive body of research examining the economic implications of intergenerational wealth transfers. The foundational works of Kotlikoff and Summers (1981) and Modigliani (1988) initiated the exploration of this topic. The research conducted by Piketty (2011) and Piketty (2014) revitalized interest in the impact of unequal intergenerational wealth transfers. For instance, studies by Black et al. (2020) and Fagereng et al. (2021) have investigated the role of these transfers in shaping the wealth and other economic outcomes of the next generation. Furthermore, researchers such as Boserup et al. (2016), Adermon et al. (2018), Elinder et al. (2018), Black et al. (2022), and Nekoei and Seim (2023)

⁶ In addition, in the studies by Freyer and Günther (2022) and Cohen et al. (2022), workers in the self-earned treatment perform identical tasks, whereas those in the passed-on treatment do not engage in any tasks. In contrast, our approach ensures that all workers across treatments perform the same tasks, with the only variable being the source of their earning determination, to maintain a *ceteris paribus* condition.

have focused on the implications of unequal intergenerational transfers on wealth inequality at an aggregate level. Additionally, [Bastani and Waldenström \(2021\)](#) examined how the providing of information regarding the effects of unequal intergenerational transfers influences public attitudes toward inheritance taxation. Our study adds to this dialogue by providing a precise measurement of public fairness perceptions concerning intergenerational wealth transfers.

2 Experimental Design

This experiment adapts the framework established by [Almås et al. \(2020\)](#), incorporating necessary modifications to align with our research objectives. The experiment involved three distinct groups: workers, their parents, and spectators. All workers were tasked with completing the same assignment. However, their initial earnings varied and were influenced by luck, performance, or parental transfers. Similarly, parents completed assignments with their initial earnings determined by luck or performance. An impartial third party, the spectators, was responsible for deciding how to redistribute the earnings among pairs of workers. The focus of this experiment was on the allocation decisions made by these spectators. The structure and implementation of the experiment are detailed below, with experimental protocols for all participant types provided in Appendix [D-F](#).

2.1 Workers and Parents

The workers in the study were students from Huazhong University of Science and Technology. Each was promised a participation fee of 30 CNY for a 15-minute experiment, with the possibility of earning additional money based on their and others' actions during the study. Parents were also offered 30 CNY for participating in a 15-minute experiment and could earn additional money based on their actions. Importantly, the payment was conditional on the participation of both students and their parents.

Before the experiment, students were instructed to coordinate with their parents to select one of the available 15-minute slots over the weekend. This arrangement allowed students to participate in the university lab and their parents to participate remotely. They were also advised to ensure their parents prepared a photograph

of an official document and a Hukou booklet for upload during the experiment to verify against the student's enrollment records.⁷ Upon arrival at the lab, students provided their parent's phone numbers, and we sent survey links to the parents. It is important to note that during the experiment, students were prohibited from using personal electronic devices, so they could not communicate with their parents during the experiment.

A total of 280 workers, along with their parents, participated in our main experiment, completing four different assignments, including math and logical reasoning questions. Upon completing all assignments, workers were informed about their compensation. The earnings for each assignment were determined according to pre-established payment rules. However, to ensure workers exerted the same effort across different treatments, these rules were not disclosed to the workers before or after the assignments. Additionally, the worker was paired with another for each assignment, creating 560 unique worker pairs. We informed workers that a third party would be aware of the assignment details and the initial distribution of earnings, and this third party would have the opportunity to redistribute earnings between the two workers in each pair, thus determining their actual pay for the assignment.

Similarly, the parents completed four assignments. Upon completion, parents were informed that pre-established rules determined their earnings for each assignment. To ensure consistent effort across treatments, these rules were not disclosed to the parents either before or after the assignments.

2.2 Treatments

We implemented six between-subjects treatments, varying the sources of workers' initial earnings.

Self-earned In the Luck treatment (L), initial earnings were determined by a lottery. 50% of workers randomly received 6 points each, while the rest received none. In the Merit treatment (M), earnings were performance-based. Workers scor-

⁷ A Hukou booklet is issued per family and includes all members' births, deaths, marriages, divorces, and residential moves. Only the pages displaying all family members' names, birth dates, and family relationships are required. See Appendix F. For privacy reasons, we deleted the photograph after verification.

ing above the median among their peers received 6 points, while those below did not receive any points, maintaining a 50% chance of obtaining earnings.⁸ Points were converted to actual currency at a rate of 1 point to 1 CNY.

Intergenerational transfer decided by parents In the Merit-Parent (MP) and Luck-Parent (LP) treatments, workers' initial earnings were determined by earnings transferred from their parents. Parents completed four assignments, after which they were told their compensation would adhere to predetermined payment rules. The distinction between MP and LP rested on the point-earning rule. In the MP treatment, parents earned 15 points if their performance exceeded the median level of their peers. In the LP treatment, 50% of parents randomly received 6 points each, while the rest received none. Parents had the option to transfer 6 points to their children or retain the full amount. They were informed that this transfer would determine their child's final payment, although other factors might also play a role. Transferred points were converted into funds on the student's college card, which was usable only within the college. Parents were assured of the anonymity of their decisions.⁹

Intergenerational Transfer without parents' decisions We introduced two additional treatments, MPN and LPN, where N stands for "no choice." These treatments paralleled MP and LP, except that for parents earning 15 points, we automatically transferred 6 points to their children. We explained that the transfer would determine their child's final payment, although other factors might also play a role. The six treatments are structured as follows:

- 1) *L*: Worker's wealth inequality is attributed to luck.
- 2) *M*: Worker's wealth inequality is based on assignment performance.
- 3) *LP*: Worker's wealth inequality stems from parental transfer choices, where parents' earnings are determined by luck.
- 4) *MP*: Worker's wealth inequality originates from parental transfer choices, where parents' earnings are based on performance.

⁸ We first ranked performance based on the number of questions they answered correctly and then further ranked based on their speed.

⁹ In fact, 75% of parents chose to transfer their earnings in the experiment.

5) *LPN*: Worker’s wealth inequality stems from automatic parental transfers, with parents’ earnings determined by luck.

6) *MPN*: Worker’s wealth inequality originates from automatic parental transfers, with parents’ earnings based on performance.

2.3 Spectator

Spectators were randomly assigned to one of six treatments, each paired with a unique pair of workers. Their task was to decide whether and to what extent to redistribute the workers’ initial earnings. We emphasized that, unlike typical survey responses, their choices could significantly impact real-life outcomes, with a 10% chance of implementation.^{10,11} At the end of the experiment, spectators completed a non-incentivized survey addressing their views on inheritance tax policies, along with several background questions.

To address potential variation in worker earnings, we adopted a contingent response method, where spectators made redistribution decisions across three possible scenarios: one worker earning 6 points and the other 0 points, both earning 6 points, or both earning 0 points. Spectators were not informed of the actual scenario to ensure they considered each decision carefully.¹² To maintain clarity for international spectators, the term “points” was used instead of the local currency name. In our analysis, we focus on scenarios with unequal earnings to explore spectators’ fairness views. Hence, decisions regarding unequal distribution scenarios are constantly solicited first.

Spectators were thoroughly briefed about the conditions and information previously provided to workers and their parents. This comprehensive disclosure is crucial for interpreting our results. First, spectators knew workers did not know the

¹⁰ Charness et al. (2016) discusses the merits and drawbacks of implementing decisions for only a subset of participants versus full implementation, finding little significant difference between these approaches. More relatedly, Clot et al. (2018) find the decision in the dictator game is similar for a 10% implementation probability and 100% implementation probability.

¹¹ Six pairs were not assigned an actual spectator; instead, we simulated spectator decisions by distributing earnings equally. This was necessary because, with 5,537 spectators and a 10% implementation rate, we anticipated needing 553 pairs, yet we had 540 pairs.

¹² Brandts and Charness (2011) report that the contingent response and strategy methods typically yield similar outcomes to direct-response methods. Notably, no studies they reviewed failed to replicate treatment effects found with contingent responses using direct methods.

payment rules before or after completing their tasks. This procedure ensured spectators understood that the workers' efforts were consistent across treatments. Second, we made it clear to spectators that workers would remain uninformed about their earnings throughout the experiment. This approach aimed to minimize the influence of worker expectations on spectators' decisions.¹³ Third, spectators were not aware of the workers' nationalities, maintaining the focus on economic behaviors rather than cultural or national identity.

To address potential concerns that merely knowing how a worker's parent's earnings were determined—without actual intergenerational transfers—might affect a spectator's fairness judgments, we randomly disclosed to spectators in both the Merit (M) and Luck (L) treatments whether the parent's earnings were determined by merit or luck. Our analysis shows that this information did not influence the decisions (see Appendix Table A5 and Table A6). Therefore, in this paper, we refer to these treatments simply as M and L without specifying how the parents' earnings were determined.

The fairness judgments of spectators, who, as third parties, have no financial stake in the outcomes, serve as a robust measure of fairness and inequality perceptions (e.g., Almås et al., 2020; Andreoni et al., 2020; Cassar and Klein, 2019; Mollerstrom et al., 2015). This method, contrasting with the standard dictator game and dictator games under the veil of ignorance, offers a significant benefit. Specifically, the decisions of spectators involve no personal financial trade-offs, ensuring that observed differences in distribution choices are not due to individual material self-interests.

2.4 Rationale Behind Design Features

First, it is important to highlight the differences in our method for generating initial worker earnings compared to the approach used by Almås et al. (2020). In their study, the allocation of earnings within paired work settings was structured as a zero-sum game, where the success of one worker was directly tied to the loss of another, consistently awarding one worker 6 USD and the other none. Conversely,

¹³ However, as tested in a robustness study by Almås et al. (2020), spectators' behavior is not affected even when they know workers have been informed about their initial earnings.

our method allows both workers within the pair to earn an income, assigning earnings based on individual attributes such as each worker’s luck, merit, or earnings inherited from their parents, independent of the other worker. This design aims to naturally stimulate intergenerational transfers, where children’s receipts are solely dependent on their parents’ decisions rather than a competitive comparison with another worker’s parent. As noted by [Schaube and Strang \(2023\)](#), compared to the setting of [Almås et al. \(2020\)](#) where only one worker receives earnings, spectators are more accepting of inequality when both workers have the potential to earn.¹⁴

Second, parents’ initial earnings exceed 6 points. Hence, parents can retain a significant portion of the four intergenerational transfer treatments even after making transfers. This design contrasts sharply with the “designator” approach, where parents work solely for their children’s benefit. We included this feature to reflect the concept that parents first benefit from their earnings before deciding whether to transfer any amount to their children. Indeed, individuals may work and save for various reasons, including precautionary measures, retirement planning, and the social benefits of wealth, such as prestige and power, alongside saving for their children. However, empirical evidence to date suggests that motivations centered on personal benefits play a substantial role, while the significance of motives for saving for children remains contentious, often found to be relatively mild if not insignificant (e.g., [Horioka and Watanabe, 1997](#); [Ameriks et al., 2020](#), and others).¹⁵

2.5 Implementation of Spectator Experiment

We recruited spectators from the U.S. and China via Dynata, a prominent online sampling company with a panel of over 62 million members who receive cash and vouchers as incentives for survey participation. As noted by [Haaland et al. \(2023\)](#),

¹⁴ [Schaube and Strang \(2023\)](#) observed that redistribution decisions are influenced by whether payoffs within paired workers are interdependent, specifically whether all workers can win simultaneously. Moreover, as long as the payoff structure within the pair does not fully depend on each other, it does not matter whether the chances of winning are still partly influenced by the other worker or are completely independent of one another.

¹⁵ Furthermore, this design mirrors the real-world situation where older generations typically possess significantly higher net wealth than younger ones, particularly due to the appreciating value of their assets. For instance, according to the 2023 Survey of Consumer Finances by the Federal Reserve, the median U.S. household net worth is \$120,000. However, for Americans over 50, it is more than triple that amount.

Table 1. Background Variables for the Spectator Sample

	U.S. Sample	U.S. Pop.		China Sample	China Pop.
Demographics			Demographics		
Age	49	48	Age	39	42
% White	66	64	% Han Ethnic	95	91
% Female	51	51	% Female	53	51

% Democrat	38	31			
% Independent	29	41			
% Republican	28	28			
% Prefer not to say or don't know	6				
Number of participants	2,824			2,713	

Note: This table presents a comparison of the survey participants' characteristics against the average characteristics of both the U.S. adult population and the adult population of China. For the U.S., demographic and financial characteristics are compared to data from the 2021 American Community Survey, while political affiliations are compared to 2023 Gallup polling results. For the Chinese population, the comparison is based on statistics from the 2020 Seventh National Population Census.

Dynata is frequently utilized by researchers for conducting survey-based studies. Eligibility criteria required respondents to reside in the United States or China and be at least 18 years old. For the U.S. sample, Dynata ensured a representative sample aligned with national averages in terms of gender, age, race, and census region. In China, the sample was targeted to reflect specific demographics, including age, ethnicity, gender, city tier level, and household income. Participants completed the survey on Qualtrics, where treatment assignment and randomization were conducted at the individual level using the platform's built-in features.

To enhance the quality of survey responses, we implemented multiple strategies. Initially, an attention check was conducted to filter out inattentive participants and potential bots. Additionally, participants were required to pass a quiz on the instructions before they could proceed. We also excluded responses from participants who completed the survey in less than 2 minutes or more than 60 minutes—representing the top 1% and bottom 1% of completion times, with the median completion time being approximately 10 minutes. Moreover, we screened for straight-lining bias, where respondents might consistently choose the first or last response option in demographic questions. Our analysis showed that this bias was not prevalent across the dataset.

Table 1 displays the demographic characteristics of our survey respondents and

provides a comparison with the general adult populations in their respective countries.¹⁶ For the U.S. sample, the national average statistics are sourced from the 2021 American Community Survey and the 2023 Gallup polling results. Similarly, the population statistics for the Chinese sample draw on data from the 2020 Seventh National Population Census. While age, gender, race, census region, household income, and political affiliation in the U.S. sample generally mirror national statistics, there is an overrepresentation of college-educated respondents. Our Chinese sample seems less representative: it includes a higher proportion of college graduates, residents of first-tier cities,¹⁷ and individuals with higher household incomes. This disparity in the Chinese sample may reflect limited internet access among less advantaged groups.

To ensure representativeness and adjust for these demographic discrepancies, we present the weighted statistics in Section 3. The weighting process adjusts sample weights to ensure alignment with demographic and financial characteristics as reported by the 2021 American Community Survey for the U.S. and the 2020 Seventh National Population Census for China.¹⁸

3 Results

In this section, we outline our study’s main findings, which focus on spectator decisions in scenarios of unequal earnings distribution: high earners receive 6 points while low earners receive none.¹⁹ Section 3.1 compares outcomes between earnings self-earned (M and L treatments) and those determined by intergenerational transfers (MP and LP treatments). Section 3.2 examines the effects of intergenerational transfers without parental choice (MPN and LPN treatments). Section 3.3 provides

¹⁶ Appendix A Table A2 and Table A1 report the demographic statistics for each treatment within the country.

¹⁷ Beijing, Shanghai, Guangzhou, and Shenzhen.

¹⁸ In our analysis, we employ the numerical iterative method known as raking to compute the weights. The raking process iteratively adjusts weights assigned to each respondent until the sample distribution matches the target population characteristics across all specified variables. Weights in the China sample range from 0.9 to 3.4 and from 0.4 to 2.4 in the U.S. sample, which is considered reasonable within this statistical context.

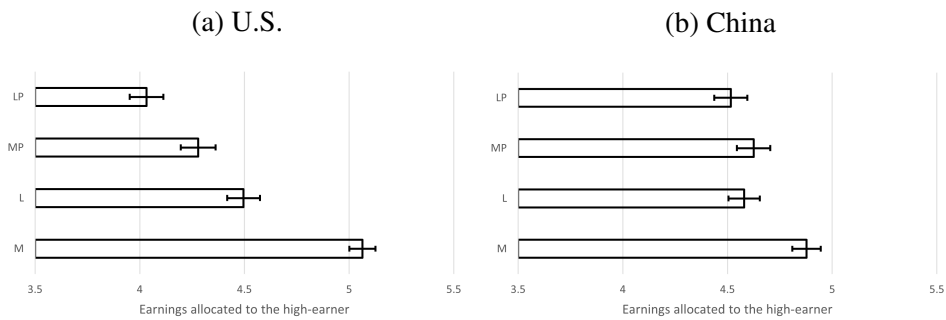

¹⁹ See Appendix C for an analysis of spectator decisions when both workers have identical earnings.

additional analyses for further robustness.

3.1 Self-Earned vs. Parent-Determined Transfers

Following the analytical framework of [Almås et al. \(2020\)](#), we first provide a descriptive overview of spectator choices and then conduct a detailed statistical analysis of treatment effects, the prevalence of different fairness views, and heterogeneity treatment effects among various demographic groups.

Figure 1: Average Level of Earnings Allocated to the High-Earner in Each of Four Treatments

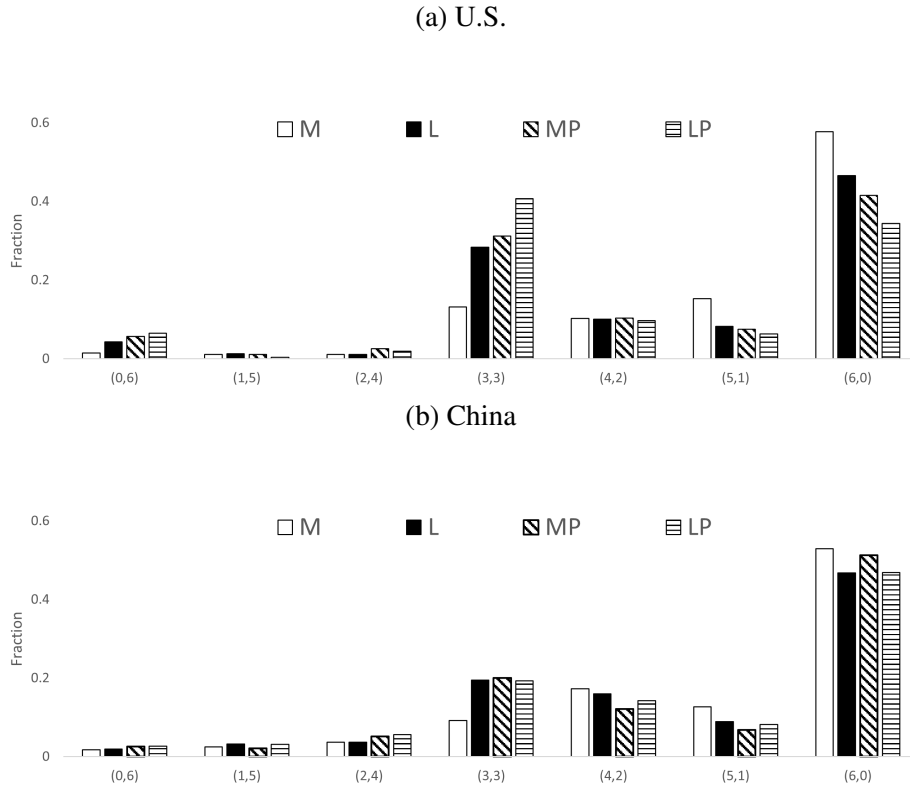

Note: This figure illustrates average level of earnings allocated to the high-earner by Americans and Chinese in each of four treatments. The robust standard errors are indicated by the bars.

Descriptive Statistics Figure 1 presents the average percentage of earnings allocated to high earners across treatments by country. Figure 2 shows histograms of spectator choices across treatments, differentiated by country. At first glance, the treatment variance of Americans is larger than that of the Chinese. Specifically, Americans allocated 84%, 75%, 71%, and 67% of total earnings to high earners in the M, L, MP, and LP treatments, respectively. Conversely, Chinese spectators allocated 81%, 76%, 77%, and 75% in the corresponding treatments.

A closer look at specific allocation decisions reveals that 59%, 47%, 42%, and 34% of American spectators awarded all 6 points to high earners in the M, L, MP, and LP treatments, respectively. The percentages for Chinese spectators were 53%, 47%, 51%, and 47%, respectively. We also analyzed the proportion of spectators who chose to distribute points equally between high and low earners. For Americans, these percentages were 13%, 28%, 31%, and 41% in the M, L, MP, and LP

Figure 2: Distribution of Spectator Choices

Note: This figure illustrates the distribution of spectator decisions by American and Chinese participants across four treatment groups. The x-axis choices (x, y) represent earnings allocations, where x indicates the earnings allocated to the lower earner and y denotes the earnings allocated to the higher earner.

treatments, respectively; for Chinese spectators, the figures were 9%, 20%, 20%, and 19%.

When comparing spectator choices between the U.S. and China, in the L treatment—where earnings are based purely on luck—there is no significant difference in the allocation to high earners between American and Chinese spectators ($p = 0.44$). However, in the M treatment, where earnings depend on individual performance, Americans allocate significantly more to high earners than do the Chinese ($p = 0.04$). Moreover, in the MP and LP treatments, where earnings stem from parental transfers, Americans allocate significantly less to high earners compared

to the Chinese ($p < 0.01$).²⁰

Treatment Effets We now examine how implemented inequality varies by treatment. The primary variable of interest is the inequality implemented by spectator i , defined as:

$$e_i = \frac{|\text{income of worker } A_i - \text{income of worker } B_i|}{\text{total income}} \in [0, 1] \quad (1)$$

Here, worker A_i represents the individual with higher pre-redistribution earnings. This inequality measure corresponds to the Gini coefficient for two-person scenarios. A value of 1 indicates no redistribution by the spectator, while a value of 0 indicates complete earning equalization between the two workers.

While Almås et al. (2020) focus primarily on implemented inequality, our analysis incorporates two additional variables to enhance the robustness of our findings: (1) the proportion of earnings allocated to the higher earner, and (2) a dummy variable indicating whether a spectator allocates more earnings to higher earners.

The main empirical approach employs a robust OLS regression:

$$y_i = \alpha + \alpha_M M_i + \alpha_{MP} MP_i + \alpha_{LP} LP_i + \gamma \mathbf{X}_i + \varepsilon_i \quad (2)$$

In this model, e_i represents one of the three main outcome variables of interest as specified, with M_i , MP_i , and LP_i serving as indicators for whether spectator i is in the Merit, Merit-Parent, or Luck-Parent treatment, respectively. The Luck treatment serves as the reference category, and estimates are interpreted relative to this baseline.

Analyses are conducted separately for samples from the U.S. and China. The vector \mathbf{X}_i includes control variables such as age, gender, race, census region, education level, household income, and political affiliation for Americans, and age, gender, ethnicity, education level, household income, and city tier level for Chinese. While our primary analysis incorporates these controls, results from regressions without control variables are also presented and discussed. Additionally, due to some discrepancies in background variables between our sample and the national

²⁰ Appendix A Table A7 provides a detailed statistical analysis of these cross-country differences.

representative samples, regression results adjusted to national norms are reported.

Table 2 presents the regression results for the U.S. sample (Panel A) and China sample (Panel B).²¹ Column titles correspond to the outcome variables examined.

Note: (1) This table displays the outcomes of robust OLS regressions examining three variables: the earnings allocated to the higher earner, a dummy variable indicating whether the spectator allocates more earnings to the higher earner, and the implemented inequality, defined as $e_i = |\text{income of worker A} - \text{income of worker B}| / \text{total income}$. Column titles indicate the outcome variables. Robust standard errors are in parentheses. (2) Regarding explanatory variables, "M", "MP", and "LP" are indicator variables taking the value 1 if the spectator is in the merit treatment, merit-parent treatment, and luck-parent treatment respectively. The reference category for these regressions is the "L" (luck) treatment. (3) Control variables for the U.S. sample include age, race, gender, education, household income, region, and political affiliation. For the Chinese sample, the controls are age, ethnic status (whether Han ethnic), gender, education, household income, and city tier level. (4) *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.

We begin by examining the estimated causal effect of replacing luck with merit as the source of inequality, facilitating comparison with existing literature. In the U.S., the effect (coefficient α_M) is positive and significant across three outcome

²¹ To conserve space, coefficients for control variables are omitted. Full estimates for the U.S. and China samples are provided in the corresponding Appendix Table A4 and A3.

variables: it increases the average earnings allocated to high earners, the probability of allocating more earnings to high earners, and the implementation of inequality. This treatment effect remains robust across all regression models, irrespective of controlling for background variables or reweighting the samples ($p < 0.01$). Conversely, in China, the shift from luck to merit as the source of inequality yields a positive but smaller and less significant effect when reweighting the sample and controlling for background variables. The reduced causal impact is consistent with findings by [Almas et al. \(2021\)](#), indicating a less pronounced sensitivity to the source of inequality (luck versus merit) among Chinese populations.

We now turn to the main findings related to intergenerational transfer to address our research questions. In the U.S., inequality acceptance is significantly higher when parents' earnings are derived from merit rather than luck, as reflected in all three outcome variables (coefficient $\alpha_{MP} - \alpha_{LP}$). However, in the Chinese sample, the difference between coefficients α_{MP} and α_{LP} is not significant, irrespective of the regression model or outcome variables used.

Furthermore, when comparing the self-earned and intergenerational contexts, American responses to inequality shift noticeably. When the source of inequality transitions from self-luck to parent-transferred wealth from parent luck, or from self-merit to parent-transferred wealth from parent merit, Americans exhibit significantly lower acceptance of inequality. The coefficients $\alpha_{MP} - \alpha_M$ and α_{LP} are negative and significant across all regression models. Notably, the level of inequality acceptance in the MP treatment is even lower than in the L treatment. However, these differences are not consistently significant across models. For the Chinese, the coefficients α_{LP} do not show significant negativity. While the difference $\alpha_{MP} - \alpha_M$ is initially significantly negative, it loses significance after sample reweighting. Based on the analysis in this section, our findings can be summarized as follows:

Result 1: *Merit, rather than luck, as the source of inequality leads to a significant increase in inequality acceptance in both the U.S. and China, with the effect being more pronounced in the U.S. sample.*

Result 2: *Americans show a preference for intergenerational meritocracy, as their acceptance of transferred inequality is higher when a parent's earnings are*

merit-based rather than luck-based. However, this preference is not observed among the Chinese.

***Result 3:** Americans exhibit a stronger aversion to inequality stemming from intergenerational wealth transfers compared to self-earned wealth. While the Chinese also show this aversion, it is much milder.*

Different Fairness Views To better understand the previously documented treatment effects, we estimate the prevalence of three common fairness views within the populations. Our approach follows methodologies from prior studies such as Cappelen et al. (2007), Almås et al. (2010), Cappelen et al. (2013), and Almås et al. (2020). The first view, egalitarian fairness, posits that it is fair for workers to receive the same earnings regardless of their initial earnings or the method by which they earn their income. The second view, meritocratic fairness, suggests that it is fair for more productive workers to receive higher earnings than less productive workers, but earning inequalities arising from luck are considered unfair. Finally, the libertarian view of fairness opposes any redistribution, regardless of whether the inequality results from luck or effort.

Previous studies have focused on self-earned wealth and used treatments similar to our L and M to estimate these three fairness views in the following ways:

- 1) *Egalitarians* are identified by the proportion of spectators who divide earnings equally in the M treatment.
- 2) *Meritocrats* are identified by the difference in the proportion of spectators who favor the more productive worker in the M treatment over those favoring the lucky worker in the L treatment.
- 3) *Libertarians* are identified by the proportion of spectators allocating all earnings to the lucky worker in the L treatment.

Spectators not classified by this approach are considered to have other preferences. We apply this classification to define and estimate three fairness views for the self-earned context, termed self-egalitarians, self-libertarians, and self-meritocrats.

Furthermore, we adapt these fairness views to the context of intergenerational wealth transfers, defining three additional categories. We first define intergener-

Figure 3: Weighted Share of the Different Fairness Types in the U.S.

Note: This figure displays the distribution of different fairness types among American spectators. The categories are based on responses to scenarios involving self-made wealth and intergenerational wealth transfers. Egalitarians are defined as spectators who enforce complete equality in the M/MP treatments. Libertarians are those who refrain from redistributing any income to lower-income workers in the L/LP treatments. The proportion of meritocrats is calculated by subtracting the percentage of spectators who allocate more to lower-income workers in the L/LP treatments from those who allocate more to higher-earning workers in the M/MP treatments. Participants not fitting into these categories are labeled as “Other.” The data are weighted to be nationally representative, and robust standard errors are represented by the bars in the figure.

ational egalitarian fairness as always equalizing unequal intergenerational wealth transfers no matter how parents get their earnings in the first place. The second view, intergenerational meritocratic fairness, respects parents’ merit: they think the inequality from transfer is fair as long as parents get their earnings based on their merit. Finally, the intergenerational libertarian view of fairness opposes any redistribution. This fairness view is identified as follows:

- 1) *Intergenerational-Egalitarians* are identified by the proportion of spectators who distribute earnings equally in the MP treatment.
- 2) *Intergenerational-Meritocrats* are identified by the difference between the proportion of spectators favoring the high-earner in the MP treatment over those in the ML treatment.
- 3) *Intergenerational-Libertarians* are identified by the share of spectators allocating all to the high-earner in the LP treatment.

The estimated results are reported in Figure 3 for U.S. samples and Figure 4 for Chinese samples. Both results were reweighted to match the national representative

Figure 4: Weighted Share of the Different Fairness Types in China

Note: This figure displays the distribution of different fairness types among Chinese spectators. The categories are based on responses to scenarios involving self-made wealth and intergenerational wealth transfers. Egalitarians are defined as spectators who enforce complete equality in the M/MP treatments. Libertarians are those who refrain from redistributing any income to lower-income workers in the L/LP treatments. The proportion of meritocrats is calculated by subtracting the percentage of spectators who allocate more to lower-income workers in the L/LP treatments from those who allocate more to higher-earning workers in the M/MP treatments. Participants not fitting into these categories are labeled as “Other.” The data are weighted to be nationally representative, and robust standard errors are represented by the bars in the figure.

samples. The unweighted results reported in the Appendix Figure A1 and Figure A2 are close to the weighted results. In both countries, we find large differences between the self-earned context (Figure 3. a and Figure 4. a) and intergenerational context (Figure 3. b and Figure 4. b) in the share of fairness views. The share of egalitarianism is significantly high in the intergenerational context relative to the self-earned context (for intergenerational egalitarianism: 31% in the U.S and 19% in China; for self-egalitarian: 13% in the U.S. and 8% in China; $p < 0.01$ for both countries).²² In addition, the share of meritocracy is significantly lower in the intergenerational context relative to the self-earned context in China but less so for Americans (for intergenerational meritocracy: 11% in the U.S and 0% in China; for self-meritocracy: 18% in the U.S. and 13% in China; $p < 0.01$ for both countries). However, for the share of libertarians, the China sample shows similar shares between self-earned context and intergenerational context (45% vs. 50%, $p > 0.1$). In contrast, the U.S. sample shows a significantly high share of such

²² The statistical analysis for comparing self-earned wealth and intergenerational wealth is reported in Appendix Table A8

preference in the self-earned context relative to the intergenerational context(47% vs. 33%, $p < 0.01$).²³

Result 4: *There are large differences in fairness views between self-earned context and intergenerational context, with significantly fewer libertarians, and more egalitarians in the United States, and significantly more egalitarians, fewer meritocrats in China.*

Heterogeneity Analysis In Appendix B, we provide a detailed analysis of the heterogeneity in treatment effects across various demographic groups. In the U.S., the aversion to unequal intergenerational wealth transfers is robust across most groups, with the notable exception of households with income more than \$100K annually. These households do not exhibit a reduced acceptance of inequality when its source is luck-based transfers compared to self-derived luck. Furthermore, the intergenerational meritocracy fairness view is also largely upheld, with the exception of high-income individuals and those with college degrees.

Conversely, in China, attitudes towards unequal intergenerational transfers across various subgroups align closely with the aggregate findings, with many subgroups showing no aversion to unequal intergenerational wealth transfers while others show mild aversion.

3.2 Transfers Without Parental Choice

In the MP and LP treatments, where parents can decide whether to transfer earnings to their child, the sources of inequality among children are twofold. First,

²³ As mentioned earlier, Almås et al. (2020) also study the American’s fairness view in the self- and context. In their estimation, the U.S. general population has 29% self-libertarian, 15% self-egalitarian, 37% self-meritocracy, and 19% others. As a comparison, we have 47% self-libertarian, 14% self-egalitarian, 20% self-meritocracy, and 25% others. The difference is that we have a smaller meritocracy and higher libertarian. What causes this difference? We propose two plausible explanations for the differences observed in our findings compared to previous studies. Firstly, a potential reason could be the timing of the survey administration. Our survey was conducted post-COVID-19, whereas the study by Cappelen et al. (2021) was conducted before the pandemic. They demonstrated that early in the COVID-19 crisis in 2021, experiences related to the pandemic increased tolerance towards inequalities resulting from luck. Secondly, as highlighted in Schaub and Strang (2023), our experimental design allowed both workers the opportunity to win a lottery, which may lead to higher acceptance of luck-driven inequality. This contrasts with the setup used by Almås et al. (2020), where the gain of one worker necessarily comes at the expense of another, potentially influencing perceptions of fairness.

some parents either perform better or are more fortunate, thus having earnings to transfer, while others do not have earnings to transfer even if they want to. Second, among parents who have the means to transfer, some choose to do so while others opt not to. In contrast, the MPN and LPN treatments eliminate room for active parental choice. Hence, people’s attitudes towards unequal intergenerational wealth transfers are solely influenced by whether parents possess wealth to transfer.

Figure 5: Average Level of Earnings Allocated to the High-Earner in Each of Six Treatments

Note: This figure illustrates average level of earnings allocated to the high-earner by Americans and Chinese in each of six treatments. The robust standard errors are indicated by the bars.

Figure 5 illustrates the average percentage of earnings allocated to high earners across all six treatments by country. Appendix Figure A3 displays histograms of spectator choices across these treatments, segmented by country. The data suggest a minimal effect of parental active choice on perceptions of fairness towards intergenerational wealth transfers, as transfers in the MP and LP treatments are comparable to those in the MPN and LPN treatments. For instance, in the U.S. sample, the average transfers to high earners in the MP, LP, MPN, and LPN treatments are 71%, 67%, 74%, and 69%, respectively. Similarly, in the Chinese sample, these figures are 77%, 75%, 77%, and 75%.

Complementing this descriptive evidence, Table 3 details regression results for Equation 2, encompassing all six treatments. The findings from the MPN and LPN treatments corroborate those from the MP and LP treatments; notably, Americans exhibit a greater acceptance of inequality in the MPN than in the LPN, a pattern not observed among Chinese. Moreover, Americans display a strong aversion to inter-

generational inequality in the MPN and LPN treatments compared to self-earned inequality in the L and M treatments.

Note: (1) This table displays the outcomes of robust OLS regressions examining three variables: the earnings allocated to the higher earner, a dummy variable indicating whether the spectator allocates more earnings to the higher earner, and the implemented inequality, defined as $e_i = |\text{income of worker A} - \text{income of worker B}| / \text{total income}$. Column titles indicate the outcome variables. Robust standard errors are in parentheses. (2) Regarding explanatory variables, "M", "MP", "LP", "MPN", and "LPN" are indicator variables taking the value 1 if the spectator is in the merit treatment, merit-parent treatment, luck-parent treatment, merit-parent-no-choice treatment, and luck-parent-no-choice treatment respectively. The reference category for these regressions is the "L" (luck) treatment. (3) Control variables for the U.S. sample include age, race, gender, education, household income, region, and political affiliation. For the Chinese sample, the controls are age, ethnic status (whether Han ethnic), gender, education, household income, and city tier level. (4) *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.

Finally, we replicate the fairness view analysis and heterogeneity analysis for the MPN and LPN treatments. The corresponding results are detailed in Appendix Figure A4 - Figure A7 and Appendix Table A9. The results are consistent with those from the MP and LP treatments.

Underlying psychological mechanism What psychological mechanisms drive the aversion to inequality resulting from intergenerational wealth transfers compared to self-earned wealth? We propose two main reasons. First, spectators might aggregate the wealth between children and parents in intergenerational transfer treatments. It reflects the reality that individuals view the tax system for self-earned earnings as inherently unfair and seek to rectify this through more pronounced redistribution in cases of transferred wealth. However, insights from recent literature and our data analysis suggest this explanation is unlikely. For instance, a recent study by [Exley and Kessler \(2024\)](#) presented an experiment environment where an individual's payoff includes multiple components. In such settings, the tendency to aggregate payoff components should be more pronounced than in our scenario, which focuses on individual components. Despite this, their experimental results indicate that spectators typically exhibit narrow equity concerns, applying fairness principles specifically to distinct components of payoffs rather than the overall financial outcomes.

Furthermore, if the aggregation conjecture were valid, we would expect a higher likelihood of spectators redistributing more than half of the wealth to low-income children in intergenerational contexts (MP, LP, MPN, LPN) compared to self-earned contexts (M and L). Contrary to this hypothesis, only a small fraction of spectators (approximately 6%) across both countries opt to allocate more than half of the total earnings to the child without initial earnings. Appendix Table A11 displays regression results, which do not support significant differences in allocation behavior between self-earned and intergenerational contexts. Additionally, in Appendix Table A10, we replicate our regression excluding spectators who allocate more to the worker without initial earnings. The results are qualitatively similar to the estimated treatment differences in Table 3 remain unaffected.

The second potential explanation concerns the negative perception of intergenerational mobility. This perception intensifies when wealthy parents, already ad-

vantaged by their wealth, continue to influence economic outcomes for future generations through these transfers. [Alesina et al. \(2018\)](#) find that perceptions of low intergenerational mobility increase support for redistribution policies. In scenarios involving intergenerational transfers, the “wealthy” parents perpetuate advantages, reinforcing the cycle of intergenerational mobility.

Finally, why do Chinese individuals only have mild aversions to inequality from intergenerational wealth transfers? In the United States, cultural values strongly emphasize individualism. This ethos supports the belief that success should stem from personal achievements rather than external factors such as family wealth. Conversely, Chinese culture, deeply influenced by Confucianism, emphasizes family harmony and obligations ([Qi, 2015](#)). Consequently, wealth transfers within families are often viewed more favorably as a continuation of support and duty across generations. This cultural perspective likely leads to a more accepting view of intergenerational wealth transfers, regarded as fulfilling familial roles and responsibilities.

3.3 Further Analysis

One might be concerned that participants misunderstood the experiment and made redistribution choices randomly, as their decisions did not affect their own payoffs. We conducted a robustness check to address these concerns. Since we applied the strategic method, we also recorded spectator allocation choices when both workers had 6 points in their initial earnings. In this scenario, irrespective of their preferences, spectators should allocate 6 points to both workers. A failure to do so could indicate randomization in their choices. In [Appendix C](#), we excluded these potentially low-quality responses and repeated the analysis presented in [Table 2](#). The findings, detailed in [Table C2](#), align with our main results, reinforcing the robustness of our conclusions.

To study whether the distributive behavior in the experiment is associated with the attitudes towards redistributive policies, we examined spectators’ views on inheritance tax at the end of the experiment. The analysis, detailed in [Appendix Table A12](#), involves a regression of attitudes towards inheritance tax on the implemented inequality, controlling for all background variables. This analysis was conducted

in two different contexts: the self-earned context (L and M treatments) and the intergenerational transfer context (MP and LP treatments).

In the U.S., Republicans, older individuals, and white participants are more likely to oppose inheritance taxes. Notably, the implemented inequality in the intergenerational context (MP and LP treatments) predicts opposition to inheritance taxes ($p < 0.01$), whereas the implemented inequalities in the self-earned context (L and M treatments) do not significantly influence tax attitudes. In China, a similar pattern emerges with some nuanced differences; there is a negative correlation between the implemented inequality in the intergenerational context and support for inheritance tax ($p < 0.05$), with no significant correlation observed in the self-earned context.

4 Discussion

Intergenerational wealth transfers, such as gifts or inheritances from parents, significantly impact wealth accumulation for younger generations at the micro-level and contribute to broader economic inequality. While much of the existing literature focuses on fairness preferences associated with self-earned wealth, this study investigates perceptions of fairness towards unequal intergenerational wealth transfers through a comprehensive survey experiment in the U.S. and China. We discover that Chinese individuals generally view inequalities resulting from intergenerational wealth transfers as similar to those derived from sheer luck, even if parental wealth was earned through effort. In contrast, American respondents exhibit a strong aversion to such inequalities, regardless of whether the wealth originates from parental effort or luck. However, they are more accepting of inequality when it is merit-based.

These findings underscore a critical distinction between self-earned and transferred wealth, with profound implications for societal attitudes toward inequality and public policy perceptions. The marked aversion to intergenerational wealth transfers, particularly in the U.S., emphasizes the need for fairness research to further explore this domain and develop robust theories that differentiate between self-earned and intergenerational contexts more effectively. This distinction is not merely academic; it has significant implications for shaping policies that address

wealth inequality.

Finally, it is important to acknowledge some limitations of our study. First, to provide clear causal evidence, our experimental design ensures that workers across treatments are perceived uniformly by spectators. However, in reality, children who receive larger transfers often possess more wealth than their peers from less affluent backgrounds, a dynamic highlighted in the literature (Feiveson and Sabelhaus, 2018). The origins of this wealth disparity are multifaceted. Wealthy parents often secure their children's early financial success through strategic educational investments, which might enhance these children's career performance. Additionally, it could be that wealthy parents provide substantial financial support, potentially reducing their children's incentive to work hard. As Andrew Carnegie famously noted, "*the parent who leaves his son enormous wealth generally deadens the talents and energies of the son, and tempts him to lead a less useful and less worthy life than he otherwise would...*" Our experimental design does not capture these nuanced details. Future studies could explore perceptions about children who receive large transfers and how these perceptions interact with fairness preferences regarding unequal intergenerational wealth transfers.

Appendix A Additional Figures and Tables

Appendix Figure A1: Unweighted Shares of Different Fairness Types in the U.S.

Note: This figure displays the distribution of different fairness types among American spectators. The categories are based on responses to scenarios involving self-made wealth and intergenerational wealth transfers. Egalitarians are defined as spectators who enforce complete equality in the M/MP treatments. Libertarians are those who refrain from redistributing any income to lower-income workers in the L/LP treatments. The proportion of meritocrats is calculated by subtracting the percentage of spectators who allocate more to lower-income workers in the L/LP treatments from those who allocate more to higher-earning workers in the M/MP treatments. Participants not fitting into these categories are labeled as “Other.” Robust standard errors are represented by the bars in the figure.

Appendix Figure A2: Unweighted Shares of Different Fairness Types in China

Note: This figure displays the distribution of different fairness types among Chinese spectators. The categories are based on responses to scenarios involving self-made wealth and intergenerational wealth transfers. Egalitarians are defined as spectators who enforce complete equality in the M/MP treatments. Libertarians are those who refrain from redistributing any income to lower-income workers in the L/LP treatments. The proportion of meritocrats is calculated by subtracting the percentage of spectators who allocate more to lower-income workers in the L/LP treatments from those who allocate more to higher-earning workers in the M/MP treatments. Participants not fitting into these categories are labeled as “Other.” Robust standard errors are represented by the bars in the figure.

Appendix Figure A3: Distribution of Spectator Choices for All Treatments

(a) U.S.

(b) China

Note: This figure illustrates the distribution of spectator decisions by American and Chinese participants across six treatment groups. The x-axis choices (x, y) represent earnings allocations, where x indicates the earnings allocated to the lower earner and y denotes the earnings allocated to the higher earner.

Appendix Figure A4: Unweighted Shares of Different Fairness Types in the Chinese Intergenerational Context

(a) Without Choice: MPN/LPN

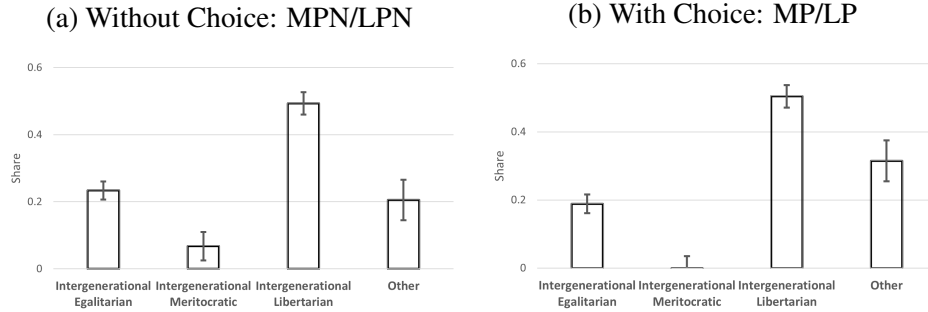

(b) With Choice: MP/LP

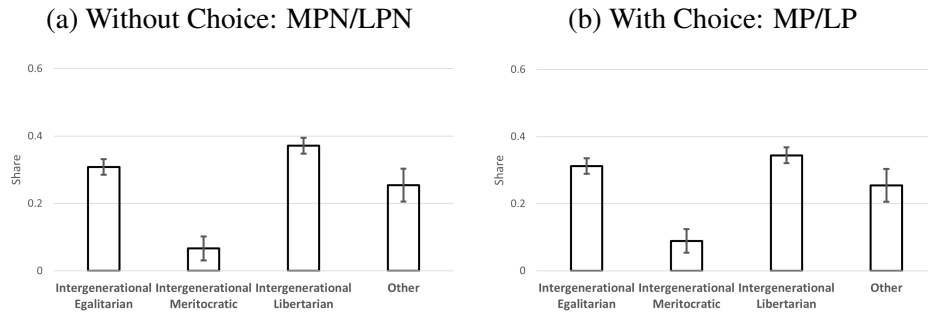

Note: This figure displays the distribution of different fairness types among Chinese spectators. The categories are based on responses to scenarios involving intergenerational wealth transfers with and without parents' own choices. Egalitarians are defined as spectators who enforce complete equality in the MPN/MP treatments. Libertarians are those who refrain from redistributing any income to lower-income workers in the LPN/LP treatments. The proportion of meritocrats is calculated by subtracting the percentage of spectators who allocate more to lower-income workers in the LPN/LP treatments from those who allocate more to higher-earning workers in the MPN/MP treatments. Participants not fitting into these categories are labeled as "Other." Robust standard errors are represented by the bars in the figure.

Appendix Figure A5: Weighted Shares of Different Fairness Types in the Chinese Intergenerational Context

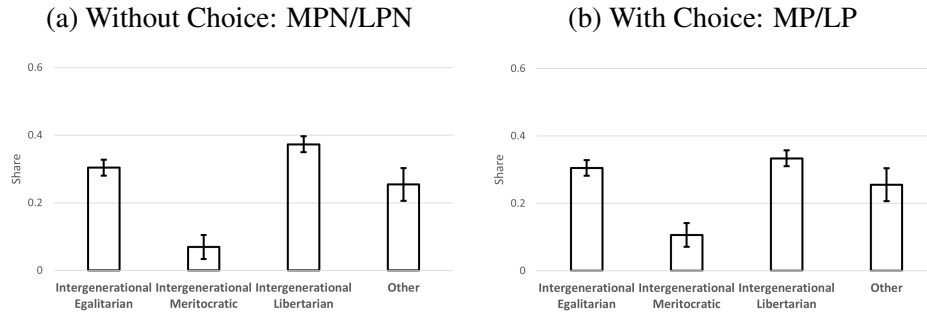

Note: This figure displays the distribution of different fairness types among Chinese spectators. The categories are based on responses to scenarios involving intergenerational wealth transfers with and without parents’ own choices. Egalitarians are defined as spectators who enforce complete equality in the MPN/MP treatments. Libertarians are those who refrain from redistributing any income to lower-income workers in the LPN/LP treatments. The proportion of meritocrats is calculated by subtracting the percentage of spectators who allocate more to lower-income workers in the LPN/LP treatments from those who allocate more to higher-earning workers in the MPN/MP treatments. Participants not fitting into these categories are labeled as “Other.” The data are weighted to be nationally representative, and robust standard errors are represented by the bars in the figure.

Appendix Figure A6: Unweighted Shares of Different Fairness Types in the Americans Intergenerational Context

Note: This figure displays the distribution of different fairness types among American spectators. The categories are based on responses to scenarios involving intergenerational wealth transfers with and without parents’ own choices. Egalitarians are defined as spectators who enforce complete equality in the MPN/MP treatments. Libertarians are those who refrain from redistributing any income to lower-income workers in the LPN/LP treatments. The proportion of meritocrats is calculated by subtracting the percentage of spectators who allocate more to lower-income workers in the LPN/LP treatments from those who allocate more to higher-earning workers in the MPN/MP treatments. Participants not fitting into these categories are labeled as “Other.” Robust standard errors are represented by the bars in the figure.

Appendix Figure A7: Weighted Shares of Different Fairness Types in the Americans Intergenerational Context

Note: This figure displays the distribution of different fairness types among American spectators. The categories are based on responses to scenarios involving intergenerational wealth transfers with and without parents’ own choices. Egalitarians are defined as spectators who enforce complete equality in the MPN/MP treatments. Libertarians are those who refrain from redistributing any income to lower-income workers in the LPN/LP treatments. The proportion of meritocrats is calculated by subtracting the percentage of spectators who allocate more to lower-income workers in the LPN/LP treatments from those who allocate more to higher-earning workers in the MPN/MP treatments. Participants not fitting into these categories are labeled as “Other.” The data are weighted to be nationally representative, and robust standard errors are represented by the bars in the figure.

Appendix Table A1. Background Variables for Different Treatments of the U.S. Spectator Sample

	U.S. Spectator Sample						U.S. Pop.
	M	L	MP	LP	MPN	LPN	
Demographics							
Age	48	49	50	50	49	47	48
% White	62	56	66	67	71	71	64
% Female	47	52	50	55	51	50	51
% Has at Least a 4-Year College Degree	45	42	46	48	49	47	33
% Northeast	19	24	19	20	17	17	18

Note: (1) This table displays the outcomes of robust OLS regressions examining three variables: the earnings allocated to the higher earner, a dummy variable indicating whether the spectator allocates more earnings to the higher earner, and the implemented inequality, defined as $e_i = |\text{income of worker A} - \text{income of worker B}| / \text{total income}$. Column titles indicate the outcome variables. Robust standard errors are in parentheses. (2) Regarding explanatory variables, “M”, “MP”, and “LP” are indicator variables taking the value 1 if the spectator is in the merit treatment, merit-parent treatment, and luck-parent treatment respectively. The reference category for these regressions is the “L” (luck) treatment. (3) Control variables for the U.S. sample include age, race, gender, education, household income, region, and political affiliation. (4) *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.

							(0.041)	(0.040)	(0.055)

Note: (1) This table presents the results of robust OLS regressions focused on different fairness views. Each column title corresponds to a specific fairness view, and robust standard errors are presented in parentheses. (2) Regarding explanatory variables, “M”, “MP”, and “LP” are indicator variables taking the value 1 if the spectator is in the merit treatment, merit-parent treatment, and luck-parent treatment respectively. The reference category for these regressions is the “L” (luck) treatment. Additionally, “Self-Earned” is an indicator variable set to 1 for spectators in either the L or M treatments, and 0 otherwise. (3) Control variables for the U.S. sample include age, race, gender, education, household income, region, and political affiliation. For the Chinese sample, the controls are age, ethnic status (whether Han ethnic), gender, education, household income, and city tier level. (4) *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.

Note: (1) This table displays the outcomes of robust OLS regressions examining three variables: the earnings allocated to the higher earner, a dummy variable indicating whether the spectator allocates more earnings to the higher earner, and the implemented inequality, defined as $e_i = |\text{income of worker A} - \text{income of worker B}|/\text{total income}$. Column titles indicate the outcome variables. Robust standard errors are in parentheses. (2) Regarding explanatory variables, “M”, “MP”, “LP”, “MPN”, and “LPN” are indicator variables taking the value 1 if the spectator is in the merit treatment, merit-parent treatment, luck-parent treatment, merit-parent-no-choice treatment, and luck-parent-no-choice treatment respectively. The reference category for these regressions is the “L” (luck) treatment. (3) Control variables for the U.S. sample include age, race, gender, education, household income, region, and political affiliation. For the Chinese sample, the controls are age, ethnic status (whether Han ethnic), gender, education, household income, and city tier level. (4) *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.

Appendix Table A11. Treatment Variations in the Likelihood of Allocating More to Low-earner

Note: (1) This table displays the outcomes of robust OLS regressions examining the correlation between spectators' policy preference and their allocation choices. and (2) For the U.S. sample, the dependent variable is the dummy variable indicating whether the spectator is strongly against inheritance tax. For the China sample, the dependent variable is the dummy variable, indicating whether spectators strongly favor inheritance tax. (3) Control variables for the U.S. sample include age, race, gender, education, household income, region, and political affiliation. For the Chinese sample, the controls are age, ethnic status (whether Han ethnic), gender, education, household income, and city tier level. (4) *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.

Appendix B Heterogeneous Analysis: Self-Earned vs. Parent-Determined Transfers

In this section, We explore heterogeneity in fairness preferences across the U.S. and China using comprehensive background data collected through our survey, with the exception of location specifics. In the U.S., our analysis focuses on variables such as political orientation, household income level, race, education level, and gender. In China, the focus shifts to ethnicity, household income, education level, and gender. This heterogeneity is examined through the following regression for each background variable:

$$y_i = \alpha + \alpha_M M_i + \alpha_{MP} MP_i + \alpha_{LP} LP_i + \alpha^B B_i + \alpha_M^B M_i \times B_i + \alpha_{MP}^B MP_i \times B_i + \alpha_{ML}^B ML_i \times B_i + \gamma \mathbf{X}_i + \varepsilon_i \quad (3)$$

Here, B_i represents an indicator variable for whether spectator i belongs to the subgroup specified in the column title. In this model, \mathbf{X}_i encompasses all background variables, excluding the variable represented by B_i . This regression includes interactions between the background indicator and treatment indicators, such as $B_i \times M_i$, $B_i \times MP_i$, and $B_i \times LP_i$.

Table B1 displays the weighted estimated results, adjusted to national representative samples. The focus is on whether treatment effects observed in Table 2 are consistent across different subgroups. For example, coefficients of $M + B \times M$, $MP + B \times MP$, and $ML + B \times ML$ reveal the treatment effects for participant subgroups like Republicans, households income over 100K USD, Whites, college graduates, and females. Conversely, coefficients of M , MP , and LP provide estimated treatment effects for their respective counterpart subgroups.

We begin our analysis with the U.S. sample. The effects of the M treatment and LP treatment are notably consistent across subgroups. Specifically, replacing luck with merit as the source of inequality results in a significant increase in inequality acceptance across all subgroups ($p < 0.01$ in all cases, except for non-white and republicans). Conversely, replacing luck with wealth transferred from a lucky

parent significantly decreases inequality acceptance across most subgroups (except households with income larger than 100K).

Appendix Table B1. Regression Results on Heterogeneity Analysis

Dependent Variable: Allocated Earnings to High-earner									
	U.S.					China

Note: (1) This table presents the results of robust OLS regressions that analyze the earnings allocated to the higher earner. Robust standard errors are detailed in parentheses. (2) The explanatory variables include “M”, “MP”, and “LP”, which are indicator variables set to 1 for participants in the merit, merit-parent, and luck-parent treatments, respectively. “L” (luck) treatment serves as the reference category. Additionally, we consider interactions with subgroups, denoted by the indicator variable “B”, which is set to 1 for participants belonging to specific subgroups identified in the column titles. All background variables from the main regression are included, except for those represented by “B”. (3) *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.

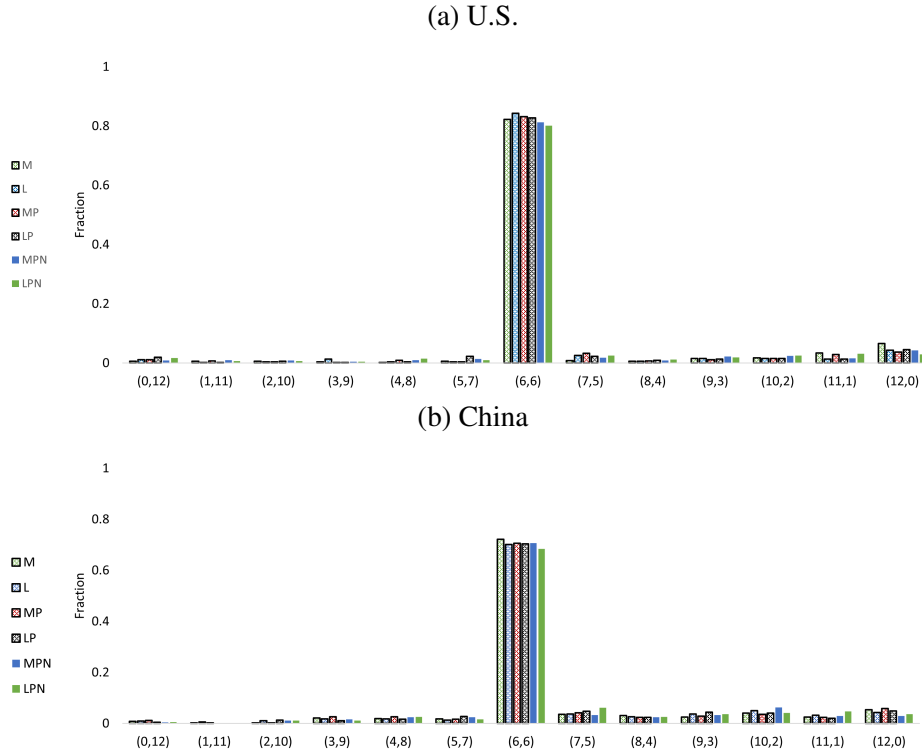

Turning to the China sample, the causal effect of replacing luck with merit as the source of inequality shows no significant impact among females, wealthy individuals with household incomes over 240K CNY, college educated, and minorities. Consistent with the main findings, most subgroups do not differentiate between inequality derived from luck or wealth transfers, regardless of the parents’ means of acquiring their wealth.

Appendix C Analysis When Both Workers Had 6 Initial Earnings

In this section, we examine how spectators distributed total earnings when each worker started with initial earnings of 6 points. When two workers are equally positioned initially, as in this scenario, it is reasonable to expect spectators to allocate 6 points to each worker. This expectation aligns with common fairness norms, including egalitarianism, meritocracy, and libertarianism.

Descriptive Analysis Figure C1 illustrates the specific allocation choices. More than 80% of American spectators distributed earnings equally between workers, and over 70% of Chinese spectators did the same. Nonetheless, a minority of spectators choose various unequal distributions even when workers began with identical initial earnings.

Appendix Figure C1: Distribution of Spectator Choices When the Initial Income of Both Workers Is 6

Note: This figure illustrates the distribution of spectator decisions by American and Chinese participants across four treatment groups. The x-axis choices (x, y) represent earnings allocations, where x indicates the earnings allocated to the lower earner and y denotes the earnings allocated to the higher earner.

Regression Analysis To determine if the likelihood of choosing an equal split remains consistent across different treatments, we conducted a robust OLS regression:

$$y_i = \alpha + \alpha_M M_i + \alpha_{MP} MP_i + \alpha_{LP} LP_i + \gamma \mathbf{X}_i + \varepsilon_i \quad (4)$$

In this model, y_i is a dummy variable indicating whether the spectator opts for an equal distribution, i.e., $(6,6)$. The variables M_i , MP_i , and LP_i indicate whether spectator i was in the Merit, Merit-Parent, or Luck-Parent treatment, respectively,

with the Luck treatment serving as the reference category. These estimates are interpreted relative to this baseline.

Analysis was conducted separately for American and Chinese samples. The vector \mathbf{X}_i includes control variables such as age, gender, race, census region, education level, household income, and political affiliation for the U.S., and age, gender, ethnicity, education level, household income, and city tier level for China. Results from regressions both with and without these control variables are presented.

Table C1 displays the regression results for both the U.S. and China samples, showing a similar propensity for equal earning distribution across treatments.

Finally, to address potential concerns that subjects who chose non-(6,6) allocations may have misunderstood the experiment instructions or selected allocations at random, we excluded these potentially low-quality responses and repeated the analysis in Table 2. The findings, detailed in Table C2, are consistent with our main results, reinforcing the robustness of our conclusions.

Controls	No	Yes	Yes	No	Yes	Yes
Weighted	No	No	Yes	No	No	Yes

Note: (1) This table displays the outcomes of robust OLS regressions examining whether spectator chooses (6,6) when the initial income of both workers is 6. Robust standard errors are in parentheses. (2) Regarding explanatory variables, “M”, “MP”, “LP”, “MPN”, and “LPN” are indicator variables taking the value 1 if the spectator is in the merit treatment, merit-parent treatment, luck-parent treatment, merit-parent-no-choice treatment, and luck-parent-no-choice treatment respectively. The reference category for these regressions is the “L” (luck) treatment. (3) Control variables for the U.S. sample include age, race, gender, education, household income, region, and political affiliation. For the Chinese sample, the controls are age, ethnic status (whether Han ethnic), gender, education, household income, and city tier level. (4) *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.

Appendix Table C2. Regression Results on Spectator Decisions for Unequal Scenario: Only Including Spectators Who Choose (6,6) When Initial Income of Both Workers is Set at 6

Panel A: U.S.

Re-weighted	No	No	Yes	No	No	Yes	No	No	Yes

Note: (1) This table displays the outcomes of robust OLS regressions examining three variables: the earnings allocated to the higher earner, a dummy variable indicating whether the spectator allocates more earnings to the higher earner, and the implemented inequality, defined as $e_i = |\text{income of worker A} - \text{income of worker B}| / \text{total income}$. Column titles indicate the outcome variables. Robust standard errors are in parentheses. (2) Regarding explanatory variables, "M", "MP", "LP", "MPN", and "LPN" are indicator variables taking the value 1 if the spectator is in the merit treatment, merit-parent treatment, luck-parent treatment, merit-parent-no-choice treatment, and luck-parent-no-choice treatment respectively. The reference category for these regressions is the "L" (luck) treatment. (3) Control variables for the U.S. sample include age, race, gender, education, household income, region, and political affiliation. For the Chinese sample, the controls are age, ethnic status (whether Han ethnic), gender, education, household income, and city tier level. (4) *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.

Appendix D Survey Instruments for Spectator

General Information

Welcome! This is an academic study on decision-making conducted by researchers.

Procedures

This study takes approximately 10 minutes, and participation is voluntary. You may drop out of this study at any time with no penalties or consequences of any kind. You are only allowed to participate in this study once.

Confidentiality

The collected data in this study will be used only for research purposes and shared in anonymized form in open science repositories in ways that will not reveal who you are. No one will be able to identify you from the shared data.

Questions

If you have questions about this study or if you have a research-related problem, you may contact the researchers at kelinluecon@gmail.com.

Consent

By participating in this study, you indicate that you are 18 years of age or older, that you understand the above information, and that you voluntarily agree to participate in this study.

Do you consent to these terms?

- No
- Yes

[[Submit]]

The next question is about the following problem. In questionnaires like ours, sometimes there are participants who do not carefully read the questions and just quickly click through the survey. This compromises the results of research studies. To show that you are reading the survey carefully, please choose both "Very strongly interested" and "Not at all interested" as your answer to the next question.

Given the above, how interested are you in football?

Very strongly interested

Very interested

A little bit interested

Not very interested

Not at all interested

[[Submit

Unlike the usual questionnaires that ask you about hypothetical scenarios, **here, your decisions will impact real people in real-life situations.** Please read the following page carefully. A quiz will test your understanding. You can proceed with the study only if you answer all quiz questions correctly.

Background Information

We recruited lots of college students and their parents to join our study. **To verify their relationship, we asked parents to present an official ID, which we then cross-checked with the student's enrollment records.** Students and their parents are guaranteed a fixed participation payment, and there's a chance to earn extra money based on what they decide during the study.

Students take part in the study in a college classroom without internet access. At the same time, their parents are in a different place doing their part. **They can't talk to each other or know what the other is doing.**

[M treatment and parents' income is also determined by merit]

Parent Decisions

Parents first worked on a quiz. After they finished, **we told parents that their income would be based on a predetermined set of payment rules. But, we didn't share what these rules were exactly.** Here's how it worked: if their performance is above the median level, they earned 15 points; if not, they got nothing. Therefore, 50% of the parents earned 15 points, while the other 50% earned none. Points will be transferred to actual money to their bank account by a fixed ratio.

Your Role in This Study:

Students also worked on the quiz assignment. Once the assignments are completed, **we pair students up. Let us consider two such paired students, whom we'll call Student A and Student B.**

Once the assignment was completed, **we told students that their initial income would be based on a predetermined set of payment rules. But, we didn't share what these rules were exactly.** Here's what you need to know about how payment works: if their performance is above the median level, they would earn 6 points and, otherwise, nothing. Therefore, 50% of them earned 6 points, while the other 50% earned none.

These points will be turned into money on the student's school card. Students can spend this money at college.

We didn't tell Student the outcome of their initial earnings. However, we told them they were paired with another student, and their combined income will be pooled. Then, selected individuals (like you) will decide to redistribute the total income, ultimately determining the students' final payoff.

You are one of the third person, and we now want **you to choose whether to redistribute the total income earned from the assignment performance between Student A and Student B.** Your decision has a 10% chance (one out of ten) of determining their final income allocation.

Your decision is completely anonymous. The students will receive the final and will not receive any further information.

Your Choices:

Before You Decide: There are **three possible outcomes for Student A and Student B's total income decided by the assignment performance.**

- They could either both earn 6 points,
- one could earn 6 points while the other earns none,
- or they could both earn no points at all.

You'll need to think about different situations. The real situation for Student A and Student B would be one of these situations.

Please think carefully about your choices, as they will have a direct impact on the students' payoff.

Situation 1: Student A did well on the assignment and got 6 points, but Student B didn't get any points.

Please state which of the following alternatives you choose:

I do not redistribute:

- student A is paid 6 Points, and student B is paid 0 Points.

I do redistribute:

- student A is paid 5 Points, and student B is paid 1 Point.
- student A is paid 4 Points, and student B is paid 2 Points.
- student A is paid 3 Points, and student B is paid 3 Points.
- student A is paid 2 Points, and student B is paid 4 Points.
- student A is paid 1 Point, and student B is paid 5 Points.
- student A is paid 0 Points, and student B is paid 6 Points.

Situation 2: Both Student A and Student B performed well and earned 6 points.

Please state which of the following alternatives you choose:

I do not redistribute:

- student A is paid 6 Points, and student B is paid 6 Points.

I do redistribute:

- student A is paid 12 Points, and student B is paid 0 Points.
- student A is paid 11 Points, and student B is paid 1 Points.
- student A is paid 10 Points, and student B is paid 2 Points.
- student A is paid 9 Points, and student B is paid 3 Points.
- student A is paid 8 Points, and student B is paid 4 Points.
- student A is paid 7 Points, and student B is paid 5 Points.

- student A is paid 5 Points, and student B is paid 7 Points.
- student A is paid 4 Points, and student B is paid 8 Points.
- student A is paid 3 Points, and student B is paid 9 Points.
- student A is paid 2 Points, and student B is paid 10 Points.
- student A is paid 1 Point, and student B is paid 11 Points.
- student A is paid 0 Points, and student B is paid 12 Points.

Situation 3: **Both Student A and Student B** earn nothing. So, you do not need to make any redistribution decisions.

[L treatment and parents' income is also determined by merit]

Parent Decisions

Parents first worked on a quiz. After they finished, **we told parents that their income would be based on a predetermined set of payment rules. But, we didn't share what these rules were exactly.** Here's how it worked: if their performance is above the median level, they earned 15 points; if not, they got nothing. Therefore, 50% of the parents earned 15 points, while the other 50% earned none. Points will be transferred to actual money to their bank account by a fixed ratio.

Your Role in This Study:

Students also worked on a quiz assignment. Once the assignments are completed, **we pair students up. Let us consider two such paired students, whom we'll call Student A and Student B.**

Once the assignment was completed, **we told students that their initial income would be based on a predetermined set of payment rules. But, we didn't share what these rules were exactly.** Here's what you need to know about how payment works: Their initial earnings will be based on a lottery, not the quiz performance. 50% of workers randomly win a lottery and receive 6 points each, while the rest receive none

These points will be turned into money on the student's school card. Students can spend this money at college.

We didn't tell Student the outcome of their initial earnings. However, we told them they were paired with another student, and their combined income will be pooled. Then, selected individuals (like you) will decide to redistribute the total income, ultimately determining the students' final payoff.

You are one of the third person, and we now want **you to choose whether to redistribute the total income earned from the random lottery between Student A and Student B.** Your decision has a 10% chance (one out of ten) of determining their final income allocation.

Your decision is completely anonymous. The students will receive the final and will not receive any further information.

Your Choices:

Before You Decide: There are **three possible outcomes for Student A and Student B's total income decided by the random lottery.**

- They could either both earn 6 points,
- one could earn 6 points while the other earns none,
- or they could both earn no points at all.

You'll need to think about different situations. The real situation for Student A and Student B would be one of these situations.

Please think carefully about your choices, as they will have a direct impact on the students' payoff.

Situation 1: By luck, Student A also won the lottery, getting 6 points, while Student B didn't win anything.

Please state which of the following alternatives you choose:

I do not redistribute:

- student A is paid 6 Points, and student B is paid 0 Points.

I do redistribute:

- student A is paid 5 Points, and student B is paid 1 Point.
- student A is paid 4 Points, and student B is paid 2 Points.
- student A is paid 3 Points, and student B is paid 3 Points.
- student A is paid 2 Points, and student B is paid 4 Points.
- student A is paid 1 Point, and student B is paid 5 Points.
- student A is paid 0 Points, and student B is paid 6 Points.

Situation 2: Both Student A and Student B win the lottery and earn 6 points by luck.

Please state which of the following alternatives you choose:

I do not redistribute:

- student A is paid 6 Points, and student B is paid 6 Points.

I do redistribute:

- student A is paid 12 Points, and student B is paid 0 Points.
- student A is paid 11 Points, and student B is paid 1 Points.
- student A is paid 10 Points, and student B is paid 2 Points.
- student A is paid 9 Points, and student B is paid 3 Points.
- student A is paid 8 Points, and student B is paid 4 Points.
- student A is paid 7 Points, and student B is paid 5 Points.
- student A is paid 5 Points, and student B is paid 7 Points.
- student A is paid 4 Points, and student B is paid 8 Points.

- student A is paid 3 Points, and student B is paid 9 Points.
- student A is paid 2 Points, and student B is paid 10 Points.
- student A is paid 1 Point, and student B is paid 11 Points.
- student A is paid 0 Points, and student B is paid 12 Points.

Situation 3: **Both Student A and Student B** earn nothing. So, you do not need to make any redistribution decisions.

[MP treatment]

Parent Decisions

Parents first worked on a quiz. After they finished, **we told parents that their income would be based on a predetermined set of payment rules. But, we didn't share what these rules were exactly.** Here's how it worked: if their performance is above the median level, they earned 15 points; if not, they got nothing. Therefore, 50% of the parents earned 15 points, while the other 50% earned none. Points will be transferred to actual money to their bank account by a fixed ratio.

[choice]

If parents earned 15 points, we asked if they would like to transfer 6 points out of 15 to their child. We explained that this transfer would determine their child's payment, although other factors might also affect the final payment. Parents who did not earn any points could not transfer funds to their children.

[no-choice]

For parents who earned 15 points, we told them we would transfer 6 points out of 15 to their child, and they would keep the remaining 9 points. We explained that this transfer would determine their child's payment, although other factors might also affect the final payment. Parents who did not earn any points could not transfer funds to their children.

These points will be turned into money on the student's school card. Students can spend this money at college, but it can't be turned back into cash. We told the parents that their kids wouldn't know what choice they made, and the transfer was completely anonymous.

Your Role in This Study:

Students also worked on a quiz assignment. Once the assignments are completed, **we pair students up. Let us consider two such paired students, whom we'll call Student A and Student B.**

Once the assignment was completed, **we told students that their initial income would be based on a predetermined set of payment rules. But, we didn't share what these rules were exactly.** Here's what you need to know about how payment works: **Earnings are not based on quiz performance. Instead, earnings depend on whether a student's parent leaves income to them. If a parent leaves income, the student receives 6 points; otherwise, they receive no points.**

These points will be turned into money on the student's school card. Students can spend this money at college.

We didn't tell Student the outcome of their initial earnings. However, we told them they were paired with another student, and their combined income will be pooled. Then, selected individuals (like you) will decide to redistribute the total income, ultimately determining the students' final payoff.

You are one of the third person, and we now want **you to choose whether to redistribute the total income earned from their own parent between Student A and Student B**. Your decision has a 10% chance (one out of ten) of determining their final income allocation.

Your decision is completely anonymous. The students will receive the final and will not receive any further information.

Your Choices:

Before You Decide: There are **three possible outcomes for Student A and Student B's total income determined by their own parent**.

- They could either both earn 6 points,
- one could earn 6 points while the other earns none,
- or they could both earn no points at all.

You'll need to think about different situations. The real situation for Student A and Student B would be one of these situations.

Please think carefully about your choices, as they will have a direct impact on the students' payoff.

Situation 1: Student A received 6 points from their parent, and Student B got none from theirs.

Please state which of the following alternatives you choose:

I do not redistribute:

- student A is paid 6 Points, and student B is paid 0 Points.

I do redistribute:

- student A is paid 5 Points, and student B is paid 1 Point.
- student A is paid 4 Points, and student B is paid 2 Points.
- student A is paid 3 Points, and student B is paid 3 Points.
- student A is paid 2 Points, and student B is paid 4 Points.
- student A is paid 1 Point, and student B is paid 5 Points.
- student A is paid 0 Points, and student B is paid 6 Points.

Situation 2: Both Student A and Student B get 6 points from their own parents.

Please state which of the following alternatives you choose:

I do not redistribute:

- student A is paid 6 Points, and student B is paid 6 Points.

I do redistribute:

- student A is paid 12 Points, and student B is paid 0 Points.
- student A is paid 11 Points, and student B is paid 1 Points.
- student A is paid 10 Points, and student B is paid 2 Points.
- student A is paid 9 Points, and student B is paid 3 Points.
- student A is paid 8 Points, and student B is paid 4 Points.
- student A is paid 7 Points, and student B is paid 5 Points.
- student A is paid 5 Points, and student B is paid 7 Points.
- student A is paid 4 Points, and student B is paid 8 Points.
- student A is paid 3 Points, and student B is paid 9 Points.
- student A is paid 2 Points, and student B is paid 10 Points.
- student A is paid 1 Point, and student B is paid 11 Points.
- student A is paid 0 Points, and student B is paid 12 Points.

Situation 3: **Both Student A and Student B** earn nothing. So, you do not need to make any redistribution decisions.

[M treatment and parents' income is also determined by luck]

Parent Decisions

Parents first worked on a quiz. After they finished, **we told parents that their income would be based on a predetermined set of payment rules. But, we didn't share what these rules were exactly.** Here's how it worked: Their initial earnings will be based on a lottery, not the quiz performance. 50% of parents randomly win a lottery and receive 15 points each, while the rest receive none. Points will be transferred to actual money to their bank account by a fixed ratio.

Your Role in This Study:

Students also worked on a quiz assignment. Once the assignments are completed, **we pair students up. Let us consider two such paired students, whom we'll call Student A and Student B.**

Once the assignment was completed, **we told students that their initial income would be based on a predetermined set of payment rules. - student A is paid 11 Points, and student B is paid 1 Points.
- student A is paid 10 Points, and student B is paid 2 Points.
- student A is paid 9 Points, and student B is paid 3 Points.
- student A is paid 8 Points, and student B is paid 4 Points.
- student A is paid 7 Points, and student B is paid 5 Points.
- student A is paid 5 Points, and student B is paid 7 Points.
- student A is paid 4 Points, and student B is paid 8 Points.

- student A is paid 3 Points, and student B is paid 9 Points.
- student A is paid 2 Points, and student B is paid 10 Points.
- student A is paid 1 Point, and student B is paid 11 Points.
- student A is paid 0 Points, and student B is paid 12 Points.

Situation 3: **Both Student A and Student B** earn nothing. So, you do not need to make any redistribution decisions.

[L treatment and parents' income is also determined by luck]

Parent Decisions

Parents first worked on a quiz. After they finished, **we told parents that their income would be based on a predetermined set of payment rules. But, we didn't share what these rules were exactly.** Here's how it worked: Their initial earnings will be based on a lottery, not the quiz performance. 50% of parents randomly win a lottery and receive 15 points each, while the rest receive none. Points will be transferred to actual money to their bank account by a fixed ratio.

Your Role in This Study:

Students also worked on a quiz assignment. Once the assignments are completed, **we pair students up. Let us consider two such paired students, whom we'll call Student A and Student B.**

Once the assignment was completed, **we told students that their initial income would be based on a predetermined set of payment rules. But, we didn't share what these rules were exactly.** Here's what you need to know about how payment works: Their initial earnings will be based on a lottery, not the quiz performance. 50% of workers randomly win a lottery and receive 6 points each, while the rest receive none.

These points will be turned into money on the student's school card. Students can spend this money at college.

We didn't tell Student the outcome of their initial earnings. However, we told them they were paired with another student, and their combined income will be pooled. Then, selected individuals (like you) will decide to redistribute the total income, ultimately determining the students' final payoff.

You are one of the third person, and we now want **you to choose whether to redistribute the total income earned from the random lottery between Student A and Student B.** Your decision has a 10% chance (one out of ten) of determining their final income allocation.

Your decision is completely anonymous. The students will receive the final and will not receive any further information.

Your Choices:

Before You Decide: There are **three possible outcomes for Student A and Student B's total income decided by the random lottery.**

- They could either both earn 6 points,
- one could earn 6 points while the other earns none,
- or they could both earn no points at all.

You'll need to think about different situations. The real situation for Student A and Student B would be one of these situations.

Please think carefully about your choices, as they will have a direct impact on the students' payoff.

Situation 1: By luck, Student A also won the lottery, getting 6 points, while Student B didn't win anything.

Please state which of the following alternatives you choose:

I do not redistribute:

- student A is paid 6 Points, and student B is paid 0 Points.

I do redistribute:

- student A is paid 5 Points, and student B is paid 1 Point.
- student A is paid 4 Points, and student B is paid 2 Points.
- student A is paid 3 Points, and student B is paid 3 Points.
- student A is paid 2 Points, and student B is paid 4 Points.
- student A is paid 1 Point, and student B is paid 5 Points.
- student A is paid 0 Points, and student B is paid 6 Points.

Situation 2: Both Student A and Student B win the lottery and earn 6 points by luck.

Please state which of the following alternatives you choose:

I do not redistribute:

- student A is paid 6 Points, and student B is paid 6 Points.

I do redistribute:

- student A is paid 12 Points, and student B is paid 0 Points.
- student A is paid 11 Points, and student B is paid 1 Points.
- student A is paid 10 Points, and student B is paid 2 Points.
- student A is paid 9 Points, and student B is paid 3 Points.
- student A is paid 8 Points, and student B is paid 4 Points.
- student A is paid 7 Points, and student B is paid 5 Points.
- student A is paid 5 Points, and student B is paid 7 Points.
- student A is paid 4 Points, and student B is paid 8 Points.

- student A is paid 3 Points, and student B is paid 9 Points.
- student A is paid 2 Points, and student B is paid 10 Points.
- student A is paid 1 Point, and student B is paid 11 Points.
- student A is paid 0 Points, and student B is paid 12 Points.

Situation 3: **Both Student A and Student B** earn nothing. So, you do not need to make any redistribution decisions.

[LP treatment]

Parent Decisions

Parents first worked on a quiz. After they finished, **we told parents that their income would be based on a predetermined set of payment rules. But, we didn't share what these rules were exactly.** Here's how it worked: Their initial earnings will be based on a lottery, not the quiz performance. **50% of parents randomly win a lottery and receive 15 points each, while the rest receive none. Points will be transferred to actual money to their bank account by a fixed ratio.**

[choice]

If parents earned 15 points, we asked if they would like to transfer 6 points out of 15 to their child. We explained that this transfer would determine their child's payment, although other factors might also affect the final payment. Parents who did not earn any points could not transfer funds to their children.

[no-choice]

For parents who earned 15 points, we told them we would transfer 6 points out of 15 to their child, and they would keep the remaining 9 points. We explained that this transfer would determine their child's payment, although other factors might also affect the final payment. Parents who did not earn any points could not transfer funds to their children.

These points will be turned into money on the student's school card. Students can spend this money at college, but it can't be turned back into cash. We told the parents that their kids wouldn't know what choice they made, and the transfer was completely anonymous.

Your Role in This Study:

Students also worked on a quiz assignment. Once the assignments are completed, **we pair students up. Let us consider two such paired students, whom we'll call Student A and Student B.**

Once the assignment was completed, **we told students that their initial income would be based on a predetermined set of payment rules. But, we didn't share what these rules were exactly.** Here's what you need to know about how payment works: **Earnings are not based on quiz performance. Instead, earnings depend on whether a student's parent leaves income to them. If a parent leaves income, the student receives 6 points; otherwise, they receive no points.**

These points will be turned into money on the student's school card. Students can spend this money at college.

We didn't tell Student the outcome of their initial earnings. However, we told them they were paired with another student, and their combined income will be pooled. Then, selected individuals (like you) will decide to redistribute the total income, ultimately determining the students' final payoff.

You are one of the third person, and we now want **you to choose whether to redistribute the total income earned from their own parent between Student A and Student B**. Your decision has a 10% chance (one out of ten) of determining their final income allocation.

Your decision is completely anonymous. The students will receive the final and will not receive any further information.

Your Choices:

Before You Decide: There are **three possible outcomes for Student A and Student B's total income determined by their own parent**.

- They could either both earn 6 points,
- one could earn 6 points while the other earns none,
- or they could both earn no points at all.

You'll need to think about different situations. The real situation for Student A and Student B would be one of these situations.

Please think carefully about your choices, as they will have a direct impact on the students' payoff.

Situation 1: Student A received 6 points from their parent, and Student B got none from theirs.

Please state which of the following alternatives you choose:

I do not redistribute:

- student A is paid 6 Points, and student B is paid 0 Points.

I do redistribute:

- student A is paid 5 Points, and student B is paid 1 Point.
- student A is paid 4 Points, and student B is paid 2 Points.
- student A is paid 3 Points, and student B is paid 3 Points.
- student A is paid 2 Points, and student B is paid 4 Points.
- student A is paid 1 Point, and student B is paid 5 Points.
- student A is paid 0 Points, and student B is paid 6 Points.

Situation 2: Both Student A and Student B get 6 points from their own parents.

Please state which of the following alternatives you choose:

I do not redistribute:

- student A is paid 6 Points, and student B is paid 6 Points.

I do redistribute:

- student A is paid 12 Points, and student B is paid 0 Points.
- student A is paid 11 Points, and student B is paid 1 Points.
- student A is paid 10 Points, and student B is paid 2 Points.
- student A is paid 9 Points, and student B is paid 3 Points.
- student A is paid 8 Points, and student B is paid 4 Points.
- student A is paid 7 Points, and student B is paid 5 Points.
- student A is paid 5 Points, and student B is paid 7 Points.
- student A is paid 4 Points, and student B is paid 8 Points.
- student A is paid 3 Points, and student B is paid 9 Points.
- student A is paid 2 Points, and student B is paid 10 Points.
- student A is paid 1 Point, and student B is paid 11 Points.
- student A is paid 0 Points, and student B is paid 12 Points.

Situation 3: **Both Student A and Student B** earn nothing. So, you do not need to make any redistribution decisions.

Open Box

We would like to know your thoughts on how to redistribute the payoff between student A and student B, **especially when they started with different earnings (0 and 6 points).**

Your response is valuable for this research project. Therefore, please take the time to respond carefully and in several sentences if needed.

Demographic for US sample

What is your current age? Please enter a number.

What is your gender?

- Male (1)
- Female (2)
- Non-binary / third gender (3)

Please choose one or more races that you consider yourself to be: Please select all that apply.

- White (1)
- Black or African American (2)
- American Indian or Alaska Native (3)
- Asian (4)
- Native Hawaiian or Other Pacific Islander (5)
- Other, please specify: (6) _____

What is the highest level of school you have completed, or the highest degree you have received?

- Less than high school (1)
- High school diploma (or equivalent) (2)
- Some college but no degree (including academic, vocational, or occupational programs) (3)
- Associate/Junior College degree (including academic, vocational, or occupational programs) (4)
- Bachelor's Degree (For example: BA, BS) (5)
- Master's Degree (For example: MA, MBA, MS, MSW) (6)
- Doctoral Degree (For example: PhD) (7)
- Professional Degree (For example: MD, JD, DDS) (8)

Generally speaking, do your political preferences lean Republican, Democrat, or Independent?

- Republican (1)
- Democrat (2)
- Independent (3)
- Prefer not to say or don't know (4)

In which state is your primary residence?

Which category represents the total combined pre-tax income of all members of your household (including you) during over the last year?

Please include money from all jobs, net income from the business, farm or rent, pensions, interest on savings or bonds, dividends, social security income, unemployment benefits, food stamps, workers compensation or disability benefits, child support, alimony, scholarships, fellowships, grants, inheritances and gifts, and any other money income received by members of your household who are 15 years of age or older.

- Less than \$10,000 (1) \$10,000 to \$19,999 (2)
- \$20,000 to \$29,999 (3)
- \$30,000 to \$39,999 (4)
- \$40,000 to \$49,999 (5)
- \$50,000 to \$59,999 (6)
- \$60,000 to \$74,999 (7)
- \$75,000 to \$99,999 (8)
- \$100,000 to \$149,999 (9)
- \$150,000 to \$199,999 (10)
- \$200,000 or more (11)

Have you ever received or do you think you might have gotten any inheritance from your parents or others?

- Yes, I've received or expect to get an inheritance.
- No, I haven't received it and don't expect to get any inheritance.

Could you please estimate the value of the inheritance you've received or anticipate receiving?

- Under \$10,000
- \$10,000 to \$50,000
- \$50,001 to \$100,000
- \$100,001 to \$500,000
- Over \$500,000

Do you plan to leave an inheritance to your child(ren)?

- Yes, I plan to leave a bequest.
- I'm considering it, but I haven't decided yet.
- No, I do not plan to leave a bequest.
- I have not considered it.

An inheritance tax is a fee charged on the assets received by individuals from someone who has passed away. How do you feel about the implementation of an inheritance tax?

- Strongly in favor
- Somewhat in favor
- Neutral / No opinion
- Somewhat against
- Strongly against

Appendix E Instruction for Worker

[Translated from Chinese]

Please read the instructions below carefully.

General Instructions:

We are academic researchers from Huazhong University of Science and Technology. The results from this experiment will be used for a research project, so it is important to read and follow all instructions carefully. Your participation will remain anonymous. We will use only your college ID to assign payments. Once we verify that your parent has correctly entered your college ID and completed their part of the study, you will receive a fixed participation fee of 30 RMB. Additionally, depending on the actions you and others take, you may earn extra money. Your parents will also be compensated for their participation. Neither you nor your parents will know each other's actions during the experiment.

In this study, you will complete 4 assignments. Each assignment includes 8 logic and math questions, and you will have 4 minutes to complete each one. Your performance on each assignment may affect your additional earnings. You have a maximum of 4 minutes to complete each assignment.

Questions:

If you have any questions about this study or encounter any research-related issues, you may contact the researchers at 2023010220@hust.edu.cn.

Consent:

By participating in this study, you confirm that you are 18 years of age or older, that you understand the above information, and that you voluntarily agree to participate in this study. You also agree to provide your college ID numbers for verification.

Do you consent to these terms?

- No

- Yes

Assignment 1

Q1: $1=5$, $2=15$, $3=215$, $4=2145$ then $5=?$

Answer: 1

Q2: Choose the most appropriate option from the given four options to fill in the blank to show a certain pattern.

Answer: C

Q3: A large watermelon is cut with a fruit knife into 9 even pieces. What is the minimum number of pieces it can be divided into?

Answer: 10

Q4: Some young employees under the age of 30 at a company signed up for a weekend language training class. The department managers unanimously agreed to hold an outdoor training exercise this weekend. All employees who signed up for the language class opposed the outdoor exercise this weekend. Therefore, we can conclude:

- A. All department managers are over 30 years old.
- B. Some department managers signed up for the weekend language training class.
- C. All employees who signed up for the weekend language training class are under 30 years old.
- D. Some young employees under 30 are not department managers.

Answer: D

Q5: One day, a customer came to Harlan's store, selected goods worth 25 yuan, and gave Harlan a 100 yuan bill. Harlan didn't have enough change, so he went to the next store, exchanged the 100 yuan for change, and gave the customer 75 yuan in change. Later, the neighbor came back saying the 100 yuan was counterfeit, and Harlan replaced it with a genuine bill. How much did Harlan lose?

Answer: 100

Q6: A pasture is known to be able to feed 27 cows for 6 days before the grass is completely consumed; 23 cows can be fed for 9 days. How many days can the pasture feed 21 cows, given the grass keeps growing?

Answer: 12

Q7: A soda costs 1 yuan per bottle, and you can exchange two empty bottles for one new soda. With 20 yuan, what is the maximum number of sodas you can drink?

Answer: 40

Q8: Human ears' sensitivity to one sound can change due to the presence of another sound. The minimum level at which a sound can be heard increases with the presence of another sound, a phenomenon known as auditory masking. According to this definition, which of the following fits the description of auditory masking?

- A. Listening to music through headphones for a long time makes the volume seem gradually lower.
- B. During a noisy break, the teacher has to speak loudly for students to hear.
- C. Humans cannot hear the ultrasound emitted by bats and other animals.
- D. In a quiet room, we can hear the ticking of a clock.

Answer: B

Assignment 2

Q1: Choose the most appropriate option from the given four options to fill in the blank to show a certain pattern.

Answer: D

Q2: "Consumption pain points" refer to the particularly unsatisfactory or troublesome aspects consumers find in using or wanting to use a product. According to this definition, which of the following does NOT belong to consumption pain points?

- A. Ms. Jiang is very particular about beauty and bought a brand of skincare products but found them inconvenient to use.
- B. Mr. Ma bought sea cucumbers for health but found them time consuming and laborious to prepare and cook.
- C. The range hood at Mr. Lin's home works well, but cleaning it is very complex and requires professional service each time.
- D. Ms. Xie bought a dress she had long wanted, but her friends said it didn't suit her after she wore it, which made her very upset.

Answer: D

Q3: In 24 hours, how many times do the hour, minute, and second hands of a clock align completely?

Answer: 2

Q4: Sequence: 1, 2, 6, 24, 120, (?). What is the next number?

Answer: 720

Q5: The composition of employees in a research institute is such that all engineers are male, not all engineers are postgraduates, and not all postgraduates are male. Therefore, we can conclude:

- A. Some males are not engineers.
- B. Some male postgraduates are engineers.
- C. Some postgraduates are male.
- D. Some males are not postgraduates.

Answer: D

Q6: Two circles have radii of 1 and 2. The smaller circle rotates around the circumference of the larger circle once. How many times does the smaller circle rotate on its own axis?

Answer: 2

Q7: The father is 40 years old this year, and his son is 12 years old. How many years later will the father's age be twice the son's age?

Answer: 16

Q8: What is the probability of getting exactly 2 heads when flipping a fair coin 3 times?

Answer: 37.5%

Assignment 3

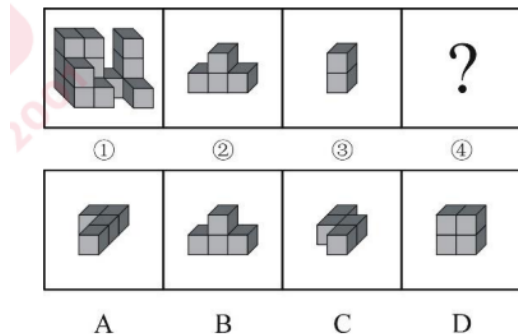

Q1: A person bought a chicken for 8 yuan and sold it for 9 yuan, then felt it was not profitable, so he bought it back for 10 yuan and sold it again for 11 yuan. How much did he make?

Answer: 2

Q2: In a family with two children, if one is a girl, what is the probability that the other is also a girl (assuming equal probability of being a boy or a girl)?

Answer: 3

Q3: Choose the most appropriate option from the given four options to fill in the blank to make the 3D shapes ①, ②, ③, and ④ form a complete rectangular box.

Answer: C

Q4: "Headline model" refers to an information service model where internet companies or media precisely push selected information with significant reference value to specific users. Which of the following belongs to the headline model?

A. After buying milk powder in a mall, Mr. Li has been receiving discount promotions for baby bathtubs, remote control toys, and children's books for three years, saving him quite a bit of money.

B. An online literature search platform provides the required literature and information such as download rates and citation rates according to user requirements, but users must provide accurate personal information.

C. An online media company divides its platform's special column content into free and paid categories, with the paid content being highly specialized, mainly for those with specific needs.

D. A new media company analyzes customer data, organizing a dedicated team to filter different types of information in real time, ensuring specific users see the content they care about first.

Answer: D

Q5: The mother's age is one of the risk factors considered in Down syndrome screening. It is generally believed that the older the mother, the higher the risk of genetic abnormalities in the baby. When there is an extra 21st chromosome in the egg, the fetus will develop Down syndrome. As women age, the risk of such abnormalities increases. Recently, some experts have begun to question this screening method, believing that genetic abnormalities are not just a matter of the woman's age. Which of the following, if true, would most support the experts' questioning?

A. Modern people are prone to gene mutations due to environmental and lifestyle influences, so even healthy couples have a risk of giving birth to a "Down's child."

B. The uterus does not significantly change with age. As long as hormone levels are sufficient, the uterus of older women can also normally nurture a fetus.

C. The main issue causing mental health problems in babies seems not to be the mother's "absolute age" but the "relative age" of the father and mother.

D. The 21st chromosome in sperm can also adhere to extra genetic material, increasing the likelihood of errors in sperm production as the father's age increases.

Answer: D

Q6: Sequence: 1, 1, 2, 3, 5, 8, ... What is the next number?

Answer: 13

Q7: In a classroom with 8 students, each student shakes hands once with any other two students. How many handshakes occurred in total?

Answer: 56

Q8: If five people can complete a task in seven days, how many days will it take if seven people work on the same task?

Answer: 5

Assignment 4

Q1: Choose the most appropriate option from the given four options to fill in the blank to show a certain pattern.

口	土	目	木	由	丰	日	?
里 中 二 月							
A		B		C		D	

Answer: D

Q2: "Hidden hunger" refers to a condition where the body suffers from an imbalance of nutrients or lacks certain vitamins and essential minerals while other nutrients are excessively consumed, leading to a hidden demand for specific nutrients. According to this definition, which of the following best fits the description of hidden hunger?

- A. Mr. Chen decided to diet and recently replaced his main meals with vegetables and apples, avoiding oily foods, eventually fainting from hunger.
- B. Xiao Bai insists on six small meals a day for a fit body, each containing staple foods, vegetables, fruits, and dairy, but still feels sore and exhausted due to high-intensity exercise.
- C. Mr. Wang, with a weak stomach, relies on porridge and soup for nourishment, avoiding heavy meats and cold fruits, eventually suffering from memory loss due to a lack of protein and vitamins.
- D. Xiao Li loves high-salt, high-sugar, and high-calorie junk food, ignoring doctors' advice, later being diagnosed with high blood sugar, high cholesterol, and high blood pressure.

Answer: C

Q3: An online shopping platform released a survey report analyzing the shopping habits of Asian women. The analysis shows that contemporary Asian women have 88% decisionmaking power in shopping for clothing and cosmetics, and 85% in shopping for home goods. Researchers therefore believe that Asian women who enjoy online shopping have greater control in their households. Which of the following, if true, best refutes this conclusion?

- A. Only about 30% of Asian women are in the habit of shopping online.

B. Some Asian women are not economically independent and do not contribute to household income.

C. The online shopping expenses of Asian women who enjoy shopping online account for only 25% of their household spending.

D. Asian women often consult with their husbands when purchasing expensive items, making joint decisions.

Answer: C

Q4: Sequence: 7, 10, 8, 11, 9, 12, ... What is the next number?

Answer: 10

Q5: If 5 workers can complete a task in 8 days, how many days will it take if 3 more workers are added to complete the same task?

Answer: 4

Q6: Two cars start from the same point, one heading north at 40 km/h and the other east at 30 km/h. What is the distance between the two cars after 1 hour?

Answer: 50 km

Q7: A farmer has chickens and cows, totaling 50 animals with a total of 140 legs. How many cows does the farmer have?

Answer: 20

Q8: If one car travels at 60 km/h and another at 80 km/h from the same point at the same time, how long will it take for the second car to be 20 km ahead of the first?

Answer: 1 hour

Payoff Determination:

For each assignment, your payment will be determined by a predetermined rule. Afterward, a randomly selected third party will have the opportunity to redistribute the earnings between you and another participant. This third party will not know your identity or that of the other participant, but they will be informed about the nature of the assignment and your respective earnings.

You will receive payments for all four assignments plus your participation fee. The money will be transferred to your college card.

Appendix F Instruction for Parent

[Translated from Chinese]

Please read the instructions below carefully.

General Instructions:

We are academic researchers from Huazhong University of Science and Technology. The results from this experiment will be used in a research project. It is important that you carefully read and follow all instructions. Your participation will remain anonymous. Once you complete the study, you will receive a fixed participation fee of 30 RMB. Depending on the actions you and others take during the experiment, you may also earn additional money.

Questions:

If you have any questions about this study or encounter any research-related issues, please contact the researchers at 2023010220@hust.edu.cn.

Consent:

By participating in this study, you confirm that you are 18 years of age or older, that you understand the information provided above, and that you voluntarily agree to participate in this study.

Do you consent to participate in this study?

- No

- Yes

[Submit]

Relationship Verification

As your child may have already informed you, they are also participating in this study simultaneously at their school. Neither you nor your child will know what the other is doing during the experiment. Your child will receive their payment once we verify that you (the parent) are also participating in the experiment.

- Please enter your child's college ID below:

- Now, please upload a picture of the relevant page from your Hukou booklet. We will immediately delete the picture after verifying the information with your child's student enrollment record at school.

name gender date of birth hukou type location change seal of the organizer

Task Instructions

In this study, you will need to complete 4 assignments. Each assignment consists of 8 questions involving logic and mathematics. You will have a maximum of 4 minutes to complete each assignment. Your performance on these assignments may determine your additional payoff.

Assignments are the same with Workers.

[Add Assignment here]

Payoff Determination

Luck:

For each assignment, your payment will be determined by a random lottery with a 50% chance of winning 15 points. Otherwise, you will receive 0 points. Each point is equivalent to 1 CNY.

Merit:

For each assignment, your payment will be based on your performance. If your performance is above the median, you will earn 15 points; otherwise, you will receive 0 points. Each point is equivalent to 1 CNY.

Transfer

For each assignment, if you earn 15 points, we would ask you whether you would like to transfer 6 of your points to your child. This transfer will determine your child's earnings from their assignment. Please note that while your decision to transfer points is crucial, other factors will also play a role in determining the final amount your child receives. Your child will not be aware of your decisions, and your choice will remain anonymous. The points you transfer, along with those earned by your child, will be converted into funds on their college card, which can only be used within the college and cannot be converted to cash.

- Would you choose to transfer 6 points to your child if you earn 15 points?
 - No
 - Yes

Transfer no choice

For each assignment, if you earn 15 points, we will transfer 6 of your points to your child. This transfer will determine your child's earnings from their assignment. Please note that other factors will also play a role in determining the final amount your child receives. Your child will not be aware of your transfer. The points you transfer, along with those earned by your child, will be converted into funds on their college card, which can only be used within the college and cannot be converted to cash.
