1 Dr. Chowdhury Shameem Mahmoud and Dr. Syed Naimul Wadood are Assistant Professors and Mr. Kazi Sabbir Ahmed is Lecturer of Department of Economics at North South University, 12 Banani C/A, Kemal Ataturk Avenue, Dhaka-1213, Bangladesh. Email Correspondence: smahmoud@northsouth.edu (Dr. Chowdhury Shameem Mahmoud). Phone: +88-02-9885611~20 (Ext. 326).
ACKNOWLEDGEMENT

The research team thanks the Centre for Policy Dialogue (CPD) and the United Nations Development Programme (UNDP) for co-sponsoring this research project titled “Addressing Regional Inequality Issues in Bangladesh Public Expenditure Allocation” under the “Pro-Poor Macroeconomic Policy” initiative. The team acknowledges with appreciation technical guidance and insightful comments from Dr. Gour Gobinda Goswami, Associate Professor and Chairman and Ms. Mausumi Mahapatro Khan, Lecturer, Department of Economics, North South University. We also appreciate useful suggestions and data support from Professor Mustafizur Rahman, Dr. Uttam Kumar Deb, Dr. Khondaker Golam Moazzem and other members of the Centre for Policy Dialogue research team. We acknowledge with appreciation comments from the participants at the Seminar on the “Regional Inequality” issue at the CIRDAP Auditorium, Dhaka on 28th February 2008, where an earlier version of this paper was presented. Last but not the least we are thankful to Dr. Fahmida Akter Khatun for her cooperation throughout this study. Usual disclaimer applies.

SECTION 1: INTRODUCTION

Traditionally the Bangladesh government’s development efforts have aimed at achieving ‘equitable economic growth.’ With this aim in view, ‘poverty alleviation objectives’—where social development features prominently, particularly in terms of improvements in health and education indicators, have always been emphasized in policy strategies. One of the most important recent policy document “Unlocking the Potential: National Strategy for Accelerated Poverty Reduction” (PRSP paper), which has been extended till June 2008, embodies such strategies with great importance. The PRSP paper as well as other government documents specifically focus on reducing incidences of poverty (also see the Medium Term Budget Framework 2007-2010 documents in the Ministry of Finance web site).

Since the return to democracy in 1991, Bangladesh’s economy has achieved a steady growth rate with concomitant fall of poverty incidences at an accelerated pace. In fact, the country experienced more than 10 percentage point fall in poverty rate in between 2000 and 2005, which is indeed a commendable achievement (Table 1.1). This in fact is in line with the better performance achieved by Bangladesh in this regard over the last three decades since the independence. One feature of this development is, however, less assuring. Table 1.1 shows that the progress in terms of reductions in incidences of poverty is not taking place equally across Bangladesh and there are some regions where the situation has even worsened (Table 1.1). This might be a reflection of the fact of unequal progress in overall economic activity across regions.

SECTION 1.1: REGIONAL ECONOMIC DISPARITY IN BANGLADESH

Is this feature of disparate reduction of poverty across regions persistent overtime? How does the regions compare when viewed with other relevant indicators?

Figure 1.1 has been drawn with the Agricultural male wages (non-food) across 64 districts in a given year; here wage has been taken as a proxy variable for income for districts. Each Box Plot reflects the disparity in Agricultural male wages across districts for a specific year.² Agricultural wage is expected to embody the opportunity cost within a district determined by the overall economic activity in it. Therefore, higher is the level of agricultural wage greater is the level of economic activity and income enjoyed by a district.

In the figure 1.1, the jump in median values between the fiscal year (FY) 1994 and 1999 reflects the fact that nominal agricultural wage including the minimum, increased overtime. What is relevant to our discussion is the fact of disparity captured by the box plots here. In case of absolute parity a box plot collapses to a single point or level and higher is the differences in wages, greater would be the deviations of different levels from each other. In the FYs 2000, 2001 and 2004 we observe the median wage to be closer to first quartile than third quartile. If we compare the changes in agricultural male wages between FY 2004 and FY 2001 then clearly the nominal wage differences of maximum and third quartile wages with the median wage have increased over this time period.

Figure 1.1: Box Plot of Agricultural Male Wages (Non-food) Across Districts for Selected Years

Source: FPMU, Ministry of Food and Disaster Management, GOB

² Available data on Agricultural Male Wage (non-food) collected by Food Policy Monitoring Unit (FPMU), Ministry of Food extends till 2004.
In Figure 1.2 nominal values of the agricultural male wages have been depicted for few selected districts together with their national average across time. Although few districts have been selectively used for the sake of exposition, including other districts do not change the story that one reads from figure 1.2. The observation that we make here is that the districts for which the agricultural male wage were below national average remained so through out the period; the districts that had their wages above national average also remained above for the entire time period shown. Therefore compared to the national averages, a number of districts have been particularly vibrant in terms of the labor market wage returns (e.g. Chittagong), whilst a number of some other districts have been lagging behind consistently during the same reference period (e.g. Rangpur). If the assertion that agricultural wages reflect the opportunity cost of agricultural activity, determined by the extent of other economic opportunities within the districts, then this finding is suggestive of the fact that income disparity prevails and is persistent across the districts or regions.

**Figure 1.2: Agricultural Male Wage Rate for Some Selected Districts (1993/94 to 2003/04)**

![Graph showing agricultural male wage rates for selected districts](image)

*Source: FPMU, Ministry of Food and Disaster Management, GOB*

In the figure 1.3, bank advances in the greater districts have been examined, as this variable reflects the economic activity in the districts. Figure 1.3, provides data for bank advances in the greater districts during the reference period of 1995-96 to 2005-06. The data provides consistent rankings of the greater districts in terms of the per capita total yearly bank advances, information as forwarded by the Bangladesh Bank and documented in the B.B.S. Yearbooks (Annex Table 2 provides detailed breakdown of purposes of bank advances). We could not
exhibit data for Dhaka, Chittagong and Khulna as they were outlier cases with rapid expansion trajectories all throughout the reference period.

**Figure 1.3: Per Capita Bank Advances in the Greater Districts, 1995-96 to 2005-06, Yearly Total**

Source: Statistical Yearbook of Bangladesh (Various Years), B.B.S.

Note: Dhaka, Chittagong and Khulna, not shown.

If one explores this issue of regional inequality further, one would find that, not only that it exists, but it can even be argued that this would persist for the immediate future, as some information would indicate. Figure 1.4 plots the per capita regional GDP in 1995-96 as against the annual trend growth rate of per capita regional GDP of the greater districts during 1995-96 to 2005-06. A distinct downward-sloping line would imply that a higher per capita regional GDP in a particular greater district is associated with a lower annual trend growth rate of the regional per capita GDP in that district during the reference period, and similarly a lower per capita regional GDP is associated with a higher annual trend growth rate of per capita regional GDP. Therefore a distinct downward-sloping pattern in the scatter plot would have implied that the economically backward regions would “catch up” with the economically advanced regions, as time progresses. In Figure 1.4, a scatter plot of 19 greater districts (excluding the Chittagong Hill Tracts) fails to exhibit any clear-cut pattern rather than a formation of a cluster with a few outlier cases. This implies that data for the reference period does not provide support for the hypothesis of “regional convergence” in the country during the same reference period.
SECTION 1.2: PUBLIC EXPENDITURE AND REGIONAL INEQUALITY

It can be argued that the rapid rise in government spending particularly in the areas of infrastructure development, health and education acted as a major force behind the progress made in the Bangladesh economy (the total public expenditure, which includes revenue expenditure as well as the ADP expenditure, has been in between 12.93 and 14.52 percents of the country’s GDP at current market prices in the recent years, 1995-96 to 2004-05, Annex Table 1).

It is commonly acknowledged that public expenditure can play a significant role in reducing incidences of poverty. If spent unequally public expenditure can exacerbate the existing imbalance in growth and poverty reduction. Therefore, it is a reasonable concern among the development practitioners to investigate the issue of regional distribution of public spending. It has been alleged that inequality in the distribution of political power has often led to some extent to a disproportionate public spending, which in turn may hinder prospects of poverty reduction. The current study aims to examine whether regional inequality issues are properly addressed and if not, whether the cited allegation has any factual basis.

With this aim this report examines whether government policies have somehow contributed to aggravating regional inequality or not. Another issue relevant to be studied is the motivations behind government policies, particularly issues related to the “political market” in a parliamentary democracy. The issues of “political market” are about “sharing arrangements of the public fund pie” among competing political constituencies-- a common phenomenon within a
This study focuses on these issues. Accordingly, this report examines the declared public investments made under the Annual Development Program (ADP), and endeavors to answer the following question: *has public expenditure in Bangladesh successfully addressed the regional income inequality problem and if not, has it been influenced by some other considerations which are mainly political by nature?*

**SECTION 1.3: RESEARCH QUESTIONS**

The study examines the published ADP documents. After controlling for all the “year” and “greater district” effects and observed characteristics, it is hypothesized that economically better-off regions would have a higher ADP allocation. If this line of argument were supported, this would imply that the ADP allocations are not properly addressing the regional inequality issue. An additional line of argument is that the districts with a higher proportion of constituencies belonging to the political party (or alliances) in power would have a tendency to receive a higher ADP allocation (because of alleged “bias” created in the system of ADP allocation by the culture of democratically elected Members of Parliaments (MPs) pursuing in favor of their own respective constituencies and it is also alleged that the ruling party MPs find it easier to distort the share of the public fund pie in their favor). Therefore two particular points are of interest, 

*Hypothesis 1: economically advanced districts receive higher ADP allocations,*

*Hypothesis 2: districts with higher percentage of constituencies belonging to the party in power receive higher ADP allocations.*

**SECTION 1.4: ORGANIZATION OF THE REPORT**

The draft report has been organized as follows: Section 2 lays out the econometric modeling, methodology and data analysis issues; Section 3 analyses a number of important sectors in terms of pro-poor growth aspects of the economy in the ADP allocation and Section 4 concludes the study.
SECTION 2: ECONOMETRIC MODEL AND METHODOLOGY

The data for this study is a panel data. Since the study requires investigation of the ADP allocation declarations of the Government of Bangladesh over a substantial period of time, and distribution of this allocation among the greater districts, it automatically implies that the data requirement would be of a panel data type, a cross section over a time series, in this particular case, a series of ADP allocation lists for all the greater districts over a number of years.

Since the ADP data records the ADP allocations over time, we have a problem of dealing with the “unobserved effects”. The cause of concern with regards to the “unobserved effects” is that, if this “effect” is uncorrelated with each of the explanatory variables, then it can be treated as just another unobserved factor affecting the dependent variable in a way that is not systematically related to the observable explanatory variables, the principle area of interest for the regression analysis. On the other hand, if the “unobserved effect” is correlated with some of the explanatory variables, putting this “effect” in the error term would lead to serious flaws in estimating the regression coefficients. Hence the panel data framework provides ways to deal with the issue of this “unobserved effect”, and this is considered the biggest advantage of a panel data over either a cross section or a time series data. The crucial assumption implied in the panel data framework is that this “unobserved effect” is constant over time (Wooldridge 2000, 2002, Greene 2000). For example, in the case that the unit of observation is the “greater district”-- this “unobserved effect” may contain unobserved characteristics of a particular greater district, such as, a number of idiosyncratic features of this particular region that the researchers can not observe (for example, higher motivation level of the district stakeholders or higher skill levels, technical abilities and management structure of the local agencies, or a reputation of a particular greater district for successful implementation of ADP)-- these can be viewed as very close to constant over the period in question. In the panel data framework, there are two ways to view the “unobserved effects”, one is the “random effects”, and the other is the “fixed effects”. The “random effects” implies a zero correlation between the observed explanatory variables and the unobserved effect. On the other hand, the “fixed effects” allows for arbitrary correlation between the unobserved effect and the observed explanatory variables (Wooldridge 2002). Whether a fixed effects or a random effects specification is appropriate in a particular application, this mostly depends on results from some econometric tests, such as, the Hausman test and the Breusch and Pagan test.
We can propose the following framework of “unobserved effects” for this analysis. This framework will take into account effects from one dimension, namely, in this case, the “greater district”. This may take a form such as:

\[ pcADP_{it} = a_0 + a_i + \beta_1 X_{it} + \beta_2 MP_{it} + e_{it} \]  

(1)

--here, \( pcADP_{it} \) is the per capita ADP allocation to district \( i \) at year \( t \)

\( a_0 \) is the intercept
\( a_i \) is the “greater district” effect for greater district \( i \)
\( X_{it} \) are explanatory variables of the greater district \( i \) at year \( t \)
\( MP_{it} \) is a set of variables designed to examine alleged political inclinations of parties in power, \( e_{it} \) is the error term, and,
\( \beta_1 \) and \( \beta_2 \) are parameters to be estimated, along with fixed or random effects estimates for “greater districts”. We may have to depend on the abovementioned tests to decide on the issue of whether the “fixed effects” or “random effects” framework is an appropriate approach here.

According to the motivation behind this examination, both \( \beta_1 \) and \( \beta_2 \) are expected to be of positive signs. The argument is that, after controlling for all the unobserved effects and the “MP” variables, it is hypothesized that economically better-off regions would have a higher ADP allocation. Again the districts with a higher proportion of constituencies belonging to the political party or alliances in power would have a tendency to receive a higher ADP allocation, controlling for the income indicator, the observed and the unobserved characteristics.

The “unobserved effects regression” specification provides estimates for “unobserved effects” itself (either “random” or “fixed”). The latter will provide a particular value for a greater district, in such a way that the sum of all the values over all the districts is exactly zero. This implies that this estimate of random effects will be positive for some districts and those will be negative for some other districts, expressed in the form of a tendency of deviation from the overall national average (which is exactly placed at zero). A hypothetical district at exactly the national average would receive the model predicted value amount of allocation. A greater district with an unobserved effects estimation of positive sign implies that this district would have a tendency to receive higher allocations compared to the national average; similarly a greater district with an unobserved effects estimation of negative sign implies that this district would have a tendency to receive lower allocations compared to the national average (over the relevant time period) (Wooldridge 2000).

An additional point is that, this study includes the Hausman test to check the appropriateness of fixed effects estimation in comparison to a random effects specification. A non-acceptance of the null hypothesis in the Hausman test is considered to be a support for a
fixed effects specification (Greene 2000). On the other hand, a Breusch and Pagan test implemented after the random effects regression would lend support for the random effects specification if the null hypothesis of variance of unobserved effects being zero were rejected.

SECTION 2.1: DATA ANALYSIS

The source of information for ADP allocation declarations is the yearly publications of Annual Development Program Reports by the Planning Commission, the Government of the People’s Republic of Bangladesh. One feature of this data is that in a large number of cases, this data includes project name, initial estimated cost, expected timeframe of the project, funding sources, declaration of ADP allocation, etc. The projects are not listed according to the greater districts, which is this study’s point of interest. Therefore after classifying the projects in terms of greater districts, from their respective titles-- a large portion of projects could not be disaggregated in terms of the greater districts (also the level of disaggregation varied over time and across sectors, see Table 3.1.2, 3.2.2 and 3.4.2).

A cross-section time-series of regional income (for example, “Regional Gross Domestic Product”) is the most appropriate information to be used in this study. Data is not currently available regarding recent years’ regional GDP data since the series of information that is available in the official documents in this regard is up to the year 1999-2000. On the other hand, the Household Income and Expenditure (HIES) Surveys are of 1995-96, 2000 and 2005 (the three most recent ones), they were not panel series-- in addition, the HIES information is available up to the level of divisions, not up to the level of all the greater districts. Since the ADP declarations are available in the official documents up to as recent as 2007-08, it was felt that we needed as much updated information about regional income as possible. The Centre for Policy Dialogue (CPD) has provided us with a data on regional income, which turned out to be particularly useful in solving the data issue. The regional income data from the CPD was from 1995-96 up till the year 2005-06.

We decided not to include the Chittagong Hill Tracts (CHT) region in our regression analysis, since the CHT region has some political and security issues as well as a different topographical setting compared to all other greater districts--this requires a separate discussion.

One problem of data collection was that it was difficult to gather information on the greater districts on a yearly basis over the entire years of the data analysis section. Another problem was that there were statistically significant correlations among a number of variables on which data were available, so that they could not be included in the final regression for issues
with multicollinearity, such as, “road density “, “head count ratio (of poverty)”, “bank advances”, etc. The estimation results do not alter significantly if these alternative variables are used.

A large amount of district-level information on child education and health related issues are recorded in the “Progotir Pathey” publications by the UNICEF and the B.B.S. But these were not incorporated since we concentrated only on the “economic” aspects of the regional inequality issue, principally because of a lack of consensus among the development practitioners with regards to the weights to be given to the social and health indicators vis-à-vis the economic ones.

SECTION 3: SECTORAL ANALYSES

SECTION 3.1: RURAL DEVELOPMENT & INSTITUTIONS (RDI)

The major portion of the Rural Development and Institutions (RDI) sector allocation of the ADP is allocated to the Local Government Engineering Department (LGED). The LGED has been involved in constructing rural and urban road infrastructure and networks throughout the country (see Table 3.1.1 for the tasks implemented by the LGED). Over the last decade, other recipient agencies of the RDI ADP have been the Bangladesh Rural Development Board (BRDB), Chittagong Hill Tracts Development Board (CHTDB), Local Government Division (LGD), Rural Development Academy, Bogra (RDA, Bogra) and others. While the overall objective is rural development, the recipient departments differ in terms of assignments and objectives.

The transport sector has expanded rapidly over the last decade in government allocations (PER, 2003). As per documented by the PER, the LGED itself received 0.47, 0.52, 0.64 and 0.78 percent of the respective GDPs of the years 1997-98, 1998-99, 1999-2000 and 2000-01. Around 90 percent of the total funds received by the LGED are allocated for construction, upgrading and rehabilitation and the remaining fund is allocated for maintenance (op. cit.), this implies that the major portion is allocated for construction and upgrading, and a small portion is for maintenance.

Level of Disaggregation

The extent of disaggregation found in the RDI ADP was higher than most other sectors reported in the ADP documents. Table 3.1.2 depicts the year wise disaggregation found in the published ADP data. The Table shows that the level of disaggregation in the fiscal year 1995-96 was about 40% that increased to about 48% for the year 2000-01. For the year 2004-05, however, it declined to 27%. The average district wise disaggregation is about 35% of the total RDI ADP allocation (Table 3.1.2).

Source: Authors’ Calculations

A considerable regional disparity exists in ADP allocation in the Rural Development and Institutions (RDI) sector in Bangladesh. Table 3.1.1 lists the ranking of different districts according to the amount of ADP received in this sector in a descending order. Based on the district wise disaggregation, among the greater districts Faridpur enjoyed the largest amount of cumulative ADP, Tk. 73107.5 lakh in total, from year 1995-96 through 2007-08. It is followed by Noakhali and Sylhet with ADP amounting to Tk. 57407 and Tk. 55,622 lakh, respectively. On the other hand, the two lowest ranking greater districts, Jamalpur and Tangail, received ADP allocations of Tk. 31993 and Tk. 31354, respectively. One important fact in this list is that one politically important district, namely, Faridpur, are at the top of the greater districts in terms of RDI ADP allocation. If we take into account the differences in population in these districts and express the RDI ADP allocation in terms of per capita, then still this district ranks as the third largest RDI ADP recipient. However, as can be seen from the last column in Table 3.1.3, expressing RDI ADP in terms of per capita results in a bit of reshuffle in the original ranking in which Patuakhali replaced Faridpur as the largest recipient, placed Kushtia few levels up and brings down Dhaka to a much lower rank (see Figure 3.1.1 and 3.1.2 for ADP allocations in RDI sector in selected greater districts, the first one is in total cumulative figures and the second one is in total cumulative per capita figures).
Estimation Procedure

Following the model detailed in the methodology section, district level disaggregated ADP allocation for different years were regressed on income levels for the greater districts and proxy variables for political clout, named, MP ratio, and the vulnerability indicator (expressed as the proportion of the constituencies within the greater districts won by the ruling party with a margin of votes less than 10 percent with the second placed candidate). District wise need for ADP allocation may vary due to differences in need. To address this, the district wise disaggregated ADP allocation (the dependent variable) has been used in per capita terms. Also the regression includes variables such as “population density” (persons per square kilometers) and “area” (square kilometers), to control for these variables.

The basic idea that we wanted to check in the regressions was to find out whether the greater district-wise ADP allocation decision is affected by political clout and income level, controlling for some observable variables and unobservable variables (through the panel data regression settings). Disparity in ADP allocation may exist due to the fact that political parties view it as a way out to succeed in the next election. Even if the situation is less pessimistic, the

disparity may be caused simply by the fact that party in power controls the flow overwhelmingly. The “MP ratio” and the “vulnerability” indicator have been used to take this feature into account.

Correlation Coefficient Results

A simple correlation coefficient was pooled across the greater districts over all the years and the result is provided in Table 3.1.4. The results do not exhibit much correlation among the variables of interest-- therefore a more rigorous analysis in the form of panel data regression was conducted, which controls for a large amount of variables.

</tbody>
</table>

Source: Calculated from ADP of various years and from the Election Commission information (N=209). Data on regional GDP is collected from the CPD. Data on 19 greater districts from 1995-96 to 2005-06. (p-values of two-tailed tests of in parenthesis).

Regression Results

Given the general model structure shown in the methodology section of the current paper, additional considerations were involved in selecting specific model and estimation procedure. A simple pooled OLS procedure was discarded in favor of fixed or random effect estimation due to panel data characteristics of the dataset.

The sign for the natural log of per capita district GDP variable is statistically significant and positive. This suggests that as far the disaggregated ADP allocation in the rural development is concerned higher allocation went to the more advanced regions, controlling for population density and area as well as variables related to political influences: “mpratio” and “vulnerability”.

Referring to Table 3.1.5, we have the random effects estimation results. The model significance of the random effects regression is a value of Wald chi-squared test as 90.6. The MP ratio and the vulnerability indicator turn out to be statistically insignificant. The random effects estimations for greater districts shows a tendency over the reference period, compared to the
national average. Patuakhali district has a tendency for the highest per capita RDI allocation of 57.70 higher value compared to the national average. Jamalpur and Faridpur also show higher level of ADP investment in this sector above the national average. Barisal, Dhaka, Noakhali and Chittagong have the tendencies to receive low levels of RDI allocation per capita, with random effects estimations at -19.149, -7.744, -10.566 and -50.430, respectively, as compared to the national average (model predicted value is 61.316). The R-squared value (within) is 0.083, (between) is 0.346 and (overall) 0.18. The fraction of variance that is due to the unobserved greater district characteristics is estimated at 0.263. Both the Hausman test and the Breusch and Pagan test lend support for random effects specification for the panel regression, rather than a fixed effects specification.

SECTION 3.2: ADP IN ROAD TRANSPORT

Bangladesh currently has an extensive network of road transport. According to the World Bank website information, the total length of roads in the country is 239,226 kilometers, of which 22,378 kilometers are classified as “main” roads (including 3,723 kilometers of National Highways roads), an additional 81,670 kilometers are “classified rural roads” and the remaining 135,178 kilometers are “other rural roads”. With regards to road density, there are 2 kilometers of roads per 1,000 people and 1,662 kilometers of roads per 1,000 square kilometers of land (see Table 3.2.1 for overall national roads and highways figures).

The importance of the road transport sub-sector has been properly recognized in the government policy documents (see the PRSP Draft Report, 2005). Traditionally the Government’s transport strategy has been to support economic development by expanding linkages in the internal transport system and to promote local market integration, particularly in the rural areas (PER, 2003, pp. 87). One success story of the road transport sub-sector is that this extensive rural road network system has contributed significantly to growth and poverty reduction by diffusing agricultural technology and raising agricultural productivity and enhancing economic activity (leading to higher wages and employment) and lowering transport costs-- at the same time, road construction had had a direct employment creation effect as a large number of rural roads were constructed under the Food-for-Work and other labor-intensive rural development initiatives. On the other hand, the road transport system has faced challenges in the form of low level of repair and maintenance as well as poor overall conditions, resulting from

dependence on labor-intensive road construction technologies rather than more advanced engineering techniques (op. cit.).

Level of Disaggregation

The ADP allocation in road transport is channeled through a number of government agencies, most prominently the Roads and Highways Department. The allocations in this department are mostly directed to expansion, and to some extent, rehabilitation, of the existing roads. Maintenance expenditures are generally a small portion of the ADP allocation. As with other sectors of the Government, this sector also exhibits small amount of disaggregating by greater districts. The proportion of disaggregating that was possible varied from a meager 8.2% in the year 1995-96 up to a high 65.04% in the year 2003-04 (Table 3.2.2) -- a total of 46% of the sectoral ADP was disaggregated over the reference period. Table 3.2.2 indicates that the overall level of disaggregating increased over the later years, particularly 2001-02 onwards. The ADP reports of later years have been more elaborate in stating the name of the area and nature of work, which turned out to be particularly useful for disaggregating.

Total and Per Capita Allocations

The ADP allocations (only portion disaggregated) exhibit widespread fluctuations with regards to distribution among the greater districts (Table 3.2.3). Dhaka is the highest total cumulative road ADP allocation recipient over the reference period while Dinajpur is the lowest cumulative road ADP allocation recipient. If we take into consideration the size of the
population, Dhaka is replaced by Jamalpur in per capita terms. Dinajpur, Bogra, Jamalpur and Noakhali are the lowest road transport ADP recipient districts, both in absolute terms as well as in the per capita terms. The wide fluctuations of road transport ADP declarations to the greater districts are exhibited in Figure 3.2.1 and Figure 3.2.2, in total cumulative and per capita cumulative terms respectively. One interesting point is that a politically distinguishable greater district Bogra received very little amount in ADP road transport allocation disaggregations during the late 2000s, but has recovered moderately during the early 2000s.

Source: Authors’ Calculations

Now, referring to Figures 3.2.2 and 3.2.3, we find that, while some districts have received fluctuating ADP allocations, other districts, most notably, Dhaka, has always been receiving a substantial and yet stable ADP road allocation designated to it by name. Both per capita ADP figures and total ADP figures exhibited in the Figures indicate that the ADP allocations in this highly important sub-sector has allocated resources among different districts in a disproportionate manner (assuming the character of allocation does not substantially alter in the portion of ADP that was not disaggregated).
Correlation Coefficients

Table 3.2.4 exhibits the correlation coefficient results. A simple correlation coefficient result may not have captured a number of factors; therefore we concentrate more on the results of the panel regression analysis.

Source: Calculated from ADP of various years and from the Election Commission information (N=209). Data on regional GDP is collected from the CPD. Data on 19 greater districts from 1995-96 to 2005-06. (p-values of two-tailed tests of in parenthesis).

Estimation Procedure

With regards to the regression exercise, two regression techniques were tested. One technique is the “fixed effects specification”. Another is the “random effects regression”, with heteroskedasticity-robust standard errors in place of default standard errors is aimed at reducing probable problems of heteroskedasticity in the regressions. With results from the abovementioned tests lending support for the random effects specification, this specification was followed in the final regression.

Regression Results

In the “random effects” specification, we regress the per capita greater district ADP allocation declarations in the road transport sector on variables such as population density, area, the “mpratio” and the “vulnerability” indicators, and the natural log of per capita regional income. The per capita district income term turns out to be positive and statistically significant, this implies that, after controlling for observable variables such as the population density and the area, and the “unobserved effects”, there has been a statistically significant coefficient estimate for the per capita income term. In other words, after controlling for all these effects, the ADP road transport allocation per capita has exhibited a tendency to be more directed towards greater
districts whose per capita regional income is higher. In addition to this, the “mpratio” term has turned out to be positive and statistically significant at 10 percent level. The estimates of “unobserved effects” show an overall tendency over the reference period. The estimates are in such a way that some of the districts are above the mean value of zero and some of the other districts are below the mean value such that the sum of all the “unobserved effects” reported would be zero. So a negative value of the unobserved effect implies a tendency for a particular district to receive a less than average allocation over time, similarly a positive value implies a tendency for more allocations to move to the district. Road ADP allocations may have a tendency for regional inequality, as it is evident in the wide variations in the estimates of “unobserved effects” across districts. At the same time, the road allocation may have been somewhat influenced by political considerations. In combination with the graphs exhibiting per capita road ADP allocations in some representative districts, there may be a systematic pattern that emerges--the pattern is that a number of greater districts may not be receiving due attentions with respect to ADP investments in roads.

With regards to alleged political clouts in distribution of road ADP allocations, the model has a variable called the “MP ratio” (percentage of MPs within a greater district that belongs to the ruling party during the reference period). A second political variable that was tested was the “vulnerability ratio” (percentage of seats that belongs to the ruling party MPs where the election result had been close, such as difference between the winning MP from ruling party has won the parliament election with a difference of votes below 10% of the second-placed candidate)-- but this variable did not turn out to be statistically significant.

The random effects results have provided both expected and statistically significant signs for the natural log of per capita regional GDP and mpratio. The coefficient of the log of per capita district GDP term is 124.741 (standard error is 21.866). Here the natural log of per capita regional GDP has been used rather than the simple per capita regional GDP to reduce fluctuations in the money figures. One explanation for the statistical significance of natural log of per capita regional GDP is that the economically advanced regions are often given higher allocation declarations, controlling for some observable variables and unobserved effects; simply stating, roads and bridges are typically assigned not in the remotest of places, but typically these are built in better off regions. A statistical significance for the “mpratio” variable can be interpreted as follows-- the Members of Parliaments may have played a more prominent role in this road transport sector. A road or a bridge constructed with active “influences” by the incumbent MP is considered to be one of the key factors for the MP to be able to retain the constituency in the next election. The local MP is therefore much more concerned about a road or a bridge, principally
because this is a winning point in the next election, and at the same time, given a typically large size of this road allocation, it is much more convenient for the MP to get involved in some rent-seeking or favoritism activities; this is actually more easier if the MP is from the ruling party or the alliance in power.

SECTION 3.3: HEALTH, POPULATION AND FAMILY WELFARE

Bangladesh has made substantial progress in the provision of Health care facilities over the years. Bangladesh Public Expenditure Review (2003) reports that considerable improvement came through investment in this sector-- infant mortality rate has declined, life expectancy has increased by 14 years and spread of preventable diseases, such as polio and malaria, has been contained. Many more challenges remain still; much less progress came in reducing malnutrition of children and maternal mortality has remained very high.

The sector was included in the current study as this sector ranks high in terms of proportion of allocation in ADP. However, after disaggregation at this sector was found to be very insignificant, particularly for the years 1998 onward. Figure 3.31 depicts year wise disaggregation found in this sector for different districts. It can be seen from the graph that starting from the fiscal year 1998-99 the level of disaggregation dramatically declined below 1% and has remained below 10% for recent years. The reason behind such decline had to do with government’s decision to shift to a programmatic approach from the previous project based approach. Due to such low level of disaggregation no meaningful regression or analysis can be conducted on the basis of the disaggregated data.

Figure 3.3.1: Level of Disaggregation in the Health ADP Allocation, 1995/96 to 2007/08

Source: Authors’ Calculations

Although no direct analysis could be conducted on the basis of data, due to idiosyncrasy of this sector there are reasons to believe that public spending overtime had been regionally equitable in nature. As have been mentioned in the above, Bangladesh has been successful in
containing many preventable diseases. Success in prevention in such cases would require equity in spending; as otherwise constant migration would compromise success in any region.

The government has initiated a shift in the Health, Population and Family Welfare sector from 1998 in which project based approach has been replaced with programmatic approach. The Health and Population Sector Program (HPSP) aims at making changes which are Bangladesh wide and therefore requires investment equitably at least at the Thana levels. However, if or not equitable distribution in spending was achieved in reality can only be found through primary data collection from the field level studies.
SECTION 3.4: EDUCATION AND RELIGIOUS AFFAIRS

Bangladesh’s achievement in the education sector is quite impressive compared to other least developed countries and particularly compared to her neighbours. Government’s strong commitment to education, manifested in the fact that this sector is receiving the highest share of the public expenditure (ADP and recurrent budgets combined) for quite a number of years now, has made this possible.

Table 3.4.1: Bangladesh Public Education Expenditure

<table>
<thead>
<tr>
<th>Fiscal Year</th>

<td>1.35</td>
<td>0.80</td>
</tr>
<tr>
<td>1999-00</td>
<td>1.37</td>
<td>0.84</td>
</tr>
</tbody>
</table>

However, not all the regions of the country have witnessed similar success in education. Though all regions have seen some progress, but there is still wide variation across regions in terms of the key indicators of education and the gap is not narrowing. Under this context one may try to analyze the distribution of public investment across regions to see whether government expenditure decision has anything to do with it.

Level of Disaggregation

Unfortunately, in the Annual Development Program, the regional investment figures are not readily available. So the study team had to engage in identifying the funds directed towards each region based on the name of the project. This allowed regional disaggregation of only a very small portion of the total investment (Table 3.4.2).

Total and Per Capita Allocations

Analysis of the disaggregated data reveals that there exist significant differences in the public investment in Education and Religious Affairs across regions (Table 3.4.3). It may happen due to the fact that these regions vary in terms of size of the population. However, the variation does not go away when one looks into per capita public investment in this sector. In fact the rankings are
almost similar indicating that regions that dominate in receiving public investment also do so in per capita sense.

A look into the investment flows over time reveals that Dhaka always gets the major share of the public investment (Figure 3.4.1). This also holds true till 2004 when per capita investment flows are considered (Figure 3.4.2). After 2005 Sylhet, Mymensingh and Khulna received more public investment per person than Dhaka and other regions.

Now if one considers per capita regional gross domestic product as a measure of regional prosperity, and if the data reveals that per capita ADP spending is associated with this variable, then it may happen that the variation in public investment across regions is partly explained by regional inequality. Strength and vulnerability of the ruling party in a particular region might also play a role.

Correlation Coefficients

The results (Table 3.4.4) do indicate that the association between per capita ADP spending in this sector and per capita regional gross domestic product is moderate and positive and it is significant as well. The association between per capita ADP spending with percentage of constituencies in a region won by ruling party turns out to be very small and positive but this association is not significant. Vulnerability of the ruling party measured as percentage of seats won by the ruling party in a region where the victory margin is less than 10%, does not have any association with per capita ADP spending.

Source: Calculated from ADP of various years, and from election commission reports (N=209). Data on ADP allocation from 1995-96 to 2005-06. (p-values of two-tailed test in parenthesis)

Estimation Procedure

As per the methodology, regression of the regional variation in per capita ADP investment on the per capita regional GDP, population density, area of the greater district, percentage of constituencies within greater district with ruling party MP, and the “vulnerability indicator” (percentage of the constituencies within the greater district won by the ruling party but by a margin of votes less than ten percent) was carried out. Heteroscedasticity-consistent standard errors were used. Random effects specification was selected instead of fixed effects specification.

Regression Results

The results indicate that the pool of independent variables do explain the variation in the dependent variable (Table 3.4.5). The constant term and the coefficients of the vulnerability indicator of constituencies with the region and natural log of per capita district GDP turn out to
be significant at 1% level and the coefficients of population density and area are significant at 5% level. The sign of the coefficient of per capita GDP is positive which indicate that regions with higher level of per capita GDP tend to receive more public investment per person. The negative relationship as seen from the result between the dependent variable and the vulnerability indicator is not expected and as seen the coefficient is not economically significant. Dhaka and Kushtia are the two regions that receive significantly more public investment than the average and for Rangpur it is just the opposite. However, one has to be very cautious in interpreting these results as the analysis is carried out using a very small percent of the total spending and the estimation may suffer from omitted variable bias.

SECTION 4: CONCLUSION AND RECOMMENDATIONS

The following are the concluding points for this study.

(1) The share of ADP investment figures that can be disaggregated by regions turns out to be on the lower side and in some instances very low for the sectors considered. Actually, this task is quite challenging given the nature of the public documents, which are not user friendly. The citizens of the country requires better access to information regarding public expenditure allocation to be able to better understand the functioning of the government and its contribution to their economic well-being.

(2) The study requires further investigation into the issue at hand. It seems that one needs go to different ministries, go through their year-to-year project documents that were included in the ADP and then come up with a better data set. But this requires a more extensive data collection phase, which the present study could not do.

(3) The limited data set does indicate that these investment numbers are substantially high for Dhaka. However, once adjusted for population, the difference becomes moderate in all the sectors. This may imply that public expenditure allocation in Bangladesh has some in-built regional inequality features that, if not addressed properly, may have adverse consequences for the homogenous development of the country in the long run.
