Can Performance of Indigenous Factors Influence Growth and Globalisation?
Kui-Wai Li, Iris A.J. Pang and Michael C.M. Ng
CSGR Working Paper 215/07
January 2007

Abstract:

This paper employs a total of thirty four openness factors and indigenous factors to construct two indicators for 62 world economies for the period 1998-2002. While most globalization studies concentrated on openness factors, regression estimates and simulation studies show that sound performance in indigenous factors are crucial to an economy’s growth and globalization. Empirical evidence shows that an optimal performance in indigenous factors can be identified, and that successful globalized economies are equipped with strong performance in their indigenous factors.

CAN PERFORMANCE OF INDIGENOUS FACTORS INFLUENCE GROWTH AND GLOBALIZATION?

I Introduction

Studies on globalization show that factors that determine an economy's performance in globalization included trade and income, inequality and poverty, distortion in the factor market and child labor (Subramanian and Wei 2003; Winters 2002; Deardorff and Stern 2002; Bhagwati 2002; 2004; Aisbett 2005; Frankel 2000; Falvery and Kreickemeier 2005 and Edmonds and Pavcnik 2002). While most pro-globalization advocates (for example, Feldstein 2000) examined the impact of external or openness factors, anti-globalization advocates focused on economic sectors that have lost out in the process of globalization (Wallach and Woodall 2004; Stiglitz 2002). Fischer (2003) noted that globalization is much more than an economic phenomenon and has non-economic consequences.

Globalization indices have popularly been constructed to rank different world economies using either a non-parametric approach as in Kearney (2005) or the principal component analysis as in Andersen and Herbertsson (2005), Heshmati (2006) and Derher (2006). One commonality in these index construction is the employment of a number of external economic or openness factors, typically trade and foreign direct investment, that are grouped into several categories. Only a few domestic or indigenous factors are included in the calculation of a single globalization index.

Although the performance of the external economy is usually seen from such openness factors as the level of international trade, capital inflow and the number of tourists, the link between these openness factors and an economy’s performance in the
global community, however, depends also on how the domestic sector performed. While a more matured capital market, for example, will facilitate a greater capital flow, a more transparent, corruption-free investment environment, for example, could attract more foreign direct investment. Indigenous factors in an economy can complement the successful performance of economic openness.

This paper distinguishes indigenous factors from the openness factors. Using available data from 62 world economies for the period 1998-2002, two separate indices are constructed for openness factors and indigenous factors. Regression analysis is conducted to show how the two types of factors can impact on economic growth. To show the importance of indigenous factors and how they can exert independent influence on growth and performance in globalization, regression analysis is used to find the optimal level of performance in an economy’s indigenous factors. Lastly, the 62 world economies are mapped according to their performance in the openness factors and indigenous factors. The result shows that economies will have to achieve a certain level in their performance of the indigenous factors before they can take advantage of economic openness.

Section II uses an improved method to work out the two indices for the openness factors and indigenous factors, and the ranking of the 62 world economies. Section III gives the regression estimates, while section IV compiles an optimal level of performance in an economy’s indigenous factors and a simulation study is conducted to show how the 62 world economies performed in the two types of factors. Section V concludes the paper.
II The Two Indicators

In constructing the globalization index, Kearney (2005) has grouped openness factors into four categories of economic integration, technological connectivity, personal contacts and international engagement. We follow this classification but improve the list of openness factors by incorporating the pattern of external trade of an economy in two aspects. Namely, while an economy’s inter-industry trade is traditionally based on comparative advantage, an economy’s intra-industry trade reflects its pattern of foreign direct investment and availability of technology. Trade statistics are post-trade data that reflect the outcome of trade policies. The performance of inter-industry trade can be seen from an economy’s revealed comparative advantage (RCA) index (Balassa 1965; 1977; 1979; 1986). ¹ When the value of $RCA_{i,g}$ exceeds unity, economy $i$ is said to have a revealed comparative advantage in good $g$ at time $t$. The total number of export industries of individual economies with revealed comparative advantage greater than unity are selected and normalized ($NRCA$) to form an indicator for the economy’s inter-industry trade performance ($itTRCA$).²

In intra-industry trade, economies export and import the same good or service in a given period. Intra-industry trade reflects more on the varieties of goods the economy enjoys due to industrial diversity and technological advancement than simply on trade

---

¹ The RCA index can be calculated as: $RCA_{i,g} = \left( \left( \frac{X_{ig}}{X_{wg}} \right) / \left( \frac{X_i}{wX} \right) \right)_t$, where $X_{ig}$ denotes economy $i$’s export of commodity $g$, $X_{wg}$ is world export of commodity $g$, $X_i$ is economy $i$’s total export and $wX$ is total world exports, where $i=1,\ldots,N$, $t=1,\ldots,T$ and $g=1,\ldots,G$.

² $TRCA = \left( \frac{NRCA}{\text{MAX} \left\{ NRCA \right\}} \right)$. 
flows based on comparative advantages. The extent of global economic integration through market structure and industry pattern can be seen from the level of intra-industry trade that also reflected the outcome of investment by multinational enterprises. The intra-industry trade index ($IIT$) can be calculated as:

$$IIT_i = \left( \sum_{g} \left[ \frac{1 - \sum_{g} X_{g,i} - M_{g,i}}{\sum_{g} X_{g,i} + M_{g,i}} \right] \times 100 \right) \div \left( \sum_{g} \left[ \frac{1 - \sum_{g} X_{g,i} - M_{g,i}}{\sum_{g} X_{g,i} + M_{g,i}} \right] \times 100 \right)$$

where $X_{g,i,j}$ is the export value of good $g$ from country $i$ to country $j$, $M_{g,i,j}$ is the import value of good $g$ to country $i$ from country $j$, and $n_j$ is the total number of economy $j$'s trading partners. Equation (1) shows the weighted average of individual industry indices, where the weights are the shares of industries in total trade.3

The data used in the construction of the Openness Factors Indicator ($OFI$) come from 17 external economic openness factors grouped under six categories. There are few exceptions. For example, Hong Kong has little international engagement in government transfer and financial contribution to the United Nations Security Council missions. Although the intention is to obtain as large a number of factors as possible, the data are more constrained in the construction of the Indigenous Factors Indicator ($IFI$). Data on a total of 17 indigenous factors are classified into three broad categories. While the first category of institutional establishment is considered as proxy measures for civility, security and protection of individuals, the other two categories provide indicators on the

A total of 62 world economies have data on all or most of the openness factors and indigenous factors. Data for the three years in 1998-2001 are complete, while some 2002 data are either provisional or unavailable. Both the openness and indigenous factors are normalized on a yearly basis, as suggested in Lockwood (2004), before they are used to construct the OFI and IFI.4

We apply the principal component analysis (PCA) to the indicators yearly. There

4 The normalization formulas for the high and low value variables that represent a higher degree of openness (in OFI) and a more advanced indigenous environment (in IFI), respectively, are:
\[ V_o = (v_i - \min(v_1, ..., v_N) / (\max(v_1, ..., v_N) - \min(v_1, ..., v_N)) \}, \text{ and} \]
\[ V_i = (\max(v_1, ..., v_N) - v_i) / (\max(v_1, ..., v_N) - \min(v_1, ..., v_N)) \}, \]
\[ V_o \text{ is variable } V \text{ of economy } i \text{ at time } t. \]
are several advantages in using the PCA method. Firstly, since these indicators are likely
to be correlated, the PCA reduces these indicators to fewer variables that capture the
maximum variation. Secondly, the PCA method can commensurate on the different
measurement units of these indicators. Most importantly, the PCA method gives
data-driven weights to the indicators that form the ultimate principal components. The
principal components are extracted from the correlation matrix of the variables, in a way
that they accounted for the highest percentage of variation. The PCA is applied to each
individual year instead of applying one PCA to the whole sample period. This has the
advantage of incorporating various changes in the sample period, and can eliminate the
impact of a sudden change in any particular year that could affect other sample years.

We adopt a latent variable model and postulate that the indicator is linearly
dependent on a set of observable factors (V) and an error term (Rencher 2002). The
principal components (PCs) are computed from the following procedure:

\[
\begin{align*}
PC_1 &= \alpha_{11}V_1 + \cdots + \alpha_{1\psi}V_\psi \\
PC_2 &= \alpha_{21}V_1 + \cdots + \alpha_{2\psi}V_\psi \\
& \vdots \\
PC_L &= \alpha_{L1}V_1 + \cdots + \alpha_{L\psi}V_\psi
\end{align*}
\]

(2)

where \(\alpha_{11}, \alpha_{12}, \ldots, \alpha_{1\psi}\) are elements of eigenvector \(\alpha_i = \{\alpha_{i1}, \ldots, \alpha_{i\psi}\}\), and there are a
total of \(L\) eigenvectors, which are determined by the data. A total of \(L\) principal
components are computed using successive eigenvectors elements, \(\alpha_{11}, \alpha_{21}, \ldots, \alpha_{L1}\),
corresponding to the largest \(L\) eigenvalues, \(\lambda_1 > \lambda_2 > \cdots > \lambda_L\), of the factor correlation
matrix. The first principal component, \(PC_1\), of the linear combination with maximal
variance becomes our OFI, which is then normalized or scaled.\(^5\) The scaled OFI will take a value of unity when an economy has the best performance in its external environment. The same procedures are applied to the construction of the IFI.

In constructing the two indicators, the missing values are replaced by their nearby means.\(^6\) Different weightings are generated from a corresponding principal component analysis for economies that an entire series of a factor is missing. The methodology is an improvement on Andersen and Herbertsson (2005) and Dreher (2006). Andersen and Herbertsson (2005) used a single principal component analysis for all the data in their sample period of 1979 to 2000, and they provided rankings of economies according to the factor scores for each year generated by pooling the years over the sample period. However, taking Lockwood’s (2004) suggestion on normalization, the problem of the methodology in Anderson and Herbertsson (2005) is that the change in the ranking of one economy in a specific year would change the rankings of other economies over the whole sample period. Dreher (2006) used weightings of principal component analysis from year 2000 for the calculation of indices for each single year from 1970 to 2000. The principal component analysis is meant to give weightings that maximize the variance of the indices, but if weightings generated in 2000 are used for the indicator of all preceding years, the maximum variance effect is lost and the principal component analysis would seem meaningless.

Table 2 gives the five-year (1998-2002) average of the OFI and IFI indicators. The

\[ \text{Scaled } OFI_i = \left( \frac{OFI_i - \min \{ OFI \}}{\max \{ OFI \} - \min \{ OFI \}} \right) \]

\(^5\) In the Openness Factors Indicators, the maximum number of missing economies in the 1998-2002 sample periods is 4, and their percentage ranged between 5.9% and 11.8%. For the Indigenous Factors Indicator, the corresponding figures for the maximum number of missing economies are 40, and the percentage ranged between 5.9% and 35.3%.
ranking based on the five-year average shows that the top 10 economies in the two indices are mainly advanced economies in North America and Western Europe. Most of the remaining European Union economies are included when the scores are extended to the top 20. Singapore and Hong Kong are the only two Asian economies in the top 20 of both indicators. We observe that an economy can vary between the two indicators. For example, Japan ranked 18th in the IFI, but ranked 26th in the OFI, while Indonesia ranked 44th and 55th in OFI and IFI, respectively. Economically weaker economies tend to rank lower in the two indicators. Effectively, economies that ranked below 30th are all developing economies.

III Regression Estimates

We make use of the two indicators and postulate the hypothesis that economies with strong performance in indigenous factors do enjoy a higher rate of per capita GDP growth at different level of economic openness. We first divide the IFI into $k$ portions using percentiles, shown in Equation (3), with $N$ being the number of economies.

$$IFI_t = \left\{ \min \{IFI_t\}, \ldots, \left( (100/k)\% \times N \right)^{th} IFI_t, \ldots, \left( (100/k)\% \times N \right)^{th} IFI_t \right\},$$

$$= \left\{ \left( (k-1)\times 100/k \right)\% \times N \right)^{th} IFI_t, \ldots, \left( (k\times 100/k)\% \times N \right)^{th} IFI_t \right\}.$$

(3)

For example, we can divide the $IFI$ of year $t$ into three portions, so $k = 3$, with 33.33 percent of the economies in each portion. The first portion is made up of the minimum $IFI$ in year $t$ to the 33rd $IFI$ in year $t$. We then assign a dummy variable, $D_\kappa$, where $\kappa = 1, \ldots, k$, to each of the last $(k-1)$ portions of $IFI$, namely $D_2, \ldots, D_k$. The $D_\kappa$ dummy takes a value
of unity if \( IFI \) falls into the \( k \)th portion, otherwise it takes a value of zero. Since the \( IFI \) is a measure of the indigenous environment of an economy, and the higher the \( IFI \) value an economy has, the better is its indigenous environment. Namely, an economy with \( D_k = 1 \) has a better indigenous environment than an economy with \( D_{k-1} = 1 \).

We use the following model to examine how indigenous factors can affect the outcome of openness on growth:

\[
\ln y_{it} = \alpha + \beta_1 \ln OFI_{it} + \beta_2 \ln OFI_{it} \times D_{2, it} + \cdots + \beta_k \ln OFI_{it} \times D_{k, it} + \varepsilon_{it},
\]

where \( y_{it} \) is the real GDP per capita deflated by the purchasing power parity of economy \( i \) at time \( t \). For economy \( i \) who has the dummy \( D_k = 1 \), the regression equation become:

\[
\ln y_{it} = \alpha + \beta_1 \ln OFI_{it} + \beta_k \ln OFI_{it} + \varepsilon_{it}, \quad \text{or} \quad (4)
\]

\[
\ln y_{it} = \alpha + (\beta_1 + \beta_k) \ln OFI_{it} + \varepsilon_{it}.
\]

For another economy \( j \) which has the dummy \( D_{k-c} = 1 \), for any \( c > 0 \). In other words, when economy \( j \)'s indigenous environment is not as good as economy \( i \)'s, the regression equation become:

\[
\ln y_{jt} = \alpha + \beta_1 \ln OFI_{jt} + \beta_{k-c} \ln OFI_{jt} + \varepsilon_{jt}, \quad \text{or} \quad (6)
\]

\[
\ln y_{jt} = \alpha + (\beta_1 + \beta_{k-c}) \ln OFI_{jt} + \varepsilon_{jt}.
\]

If a higher performance in indigenous factors brings a higher marginal effect of openness on economic growth, we expect to see \( \beta_1 + \beta_{k-c} < \beta_1 + \beta_k \). Thus,
generalizing all the $k$ dummy variables, and if a better indigenous environment has a positive impact of openness on growth, we expect to see $\beta_1 < \beta_1 + \beta_2 < \beta_1 + \beta_3 < \ldots < \beta_1 + \beta_k$, suggesting that a strong performance in an economy’s indigenous factors enables an economy to benefit more from openness. We conducted two Wald tests to show the significance of the coefficient estimates. The first Wald test is to see if a low performance in the indigenous factors constrained economic growth. We propose an alternative hypothesis with $\beta_1 < 0$, which implies that if an economy has an extremely weak performance in its indigenous factors (reflected in the $IFI$ value falling into the first partition of the indicator), openness would bring negative effects on economic growth, namely:

$$
\begin{align*}
H_0^1 : & \beta_1 = 0 \\
H_a^1 : & \beta_1 < 0.
\end{align*}
$$

The second Wald test shows that an economy’s $IFI$ can significantly affect the marginal effect of an economy’s openness on its real per capita GDP growth rate:

$$
\begin{align*}
H_0^2 : & \beta_1 + \beta_\kappa = 0 \text{ for } \kappa = 2, \ldots, k. \\
H_a^2 : & \beta_1 + \beta_{\kappa-1} < \beta_1 + \beta_\kappa \text{ for } \kappa = 3, \ldots, k.
\end{align*}
$$

The alternative hypothesis, $H_a^2$, states that economies that have a better performance in their indigenous factors should benefit more from openness.

We applied the within-GLS method to estimate Equation (4), but the emergence of the singular matrix problem due probably to the short sample period led us instead to use the pooled-GLS with White-Heteroskedasticity consistent standard error and covariance.
Equation (4) is estimated with $k = 3, 4, 8$ and 10. Table 3 shows the empirical estimation of the pooled-GLS results for the 62 countries for the sample period of 1998-2002.

* = significance at 1% level.
† = significance at 5% level
All estimates with $k = 3$ and $k = 4$ in Table 3 are significant at 1 percent level. In these two cases, the estimate for $\beta_1$ is not negative, but is significantly different from zero, suggesting that a low performance in indigenous factors does not adversely affect the effect of globalization on economic growth, though this may be due to the small size of $k$. When the size of $k$ is small, the marginal effect of indigenous factors on globalization and economic growth may not be obvious. The F-tests reject the null hypothesis of Equation (4), and suggests that as economies improve the performance of their indigenous factors, the marginal effect of globalization on growth increases.

For estimates with $k = 8$ and $k = 10$, and with the exception of the insignificant estimate for $\beta_1$, all the estimates are significance at 1 percent level. For these estimated values of $k$, the estimate of $\beta_1$ is negative, which means that growth in an economy with low performance in indigenous factors can adversely be affected by globalization. Similar to the results of $k = 3$ and $k = 4$, the F-tests reject the null hypothesis. This confirms that improvement in the performance of indigenous factors in an economy can improve the marginal effect of globalization on growth.

IV Optimal Performance in Indigenous Factors

This section uses a simulation method to work out the optimal performance in the indigenous factors in order to achieve a maximum gain in economic growth. From the estimation result of $k=4, 8$ and $10$ in Table 3, we first examine economies with top scores
in $IFI$ to see if there is diminishing returns in economic openness. Hypothetical economies are compared in order to see how an economy performs in growth and globalization given a different level of performance in indigenous factors. We established two hypotheses. First, given two externally homogeneous economies (namely, economies with same performance in the $OFI$), heterogeneity in the performance of $IFI$ will lead to differences in economic growth and development. Secondly, given homogeneity in the performance of $IFI$ among different economies, those economies with a better performance in $OFI$ will result in higher economic growth.

We make use of the empirical result with $k = 10$ in Table 3 to simulate the growth of GDP per capita for a total of 100 hypothetical economies with an incremental change of 0.01 in the $IFI$ that ranged from zero to one. We set different values of the $OFI$ that are either below or above the median value. A simulated series of per capita GDP figures are generated from the empirical results with $k = 10$ in Table 3. The simulated per capita GDP growth rates are plotted against the $IFI$, and a step function is presented separately for the four values of $OFI$ (at 0.25, 0.45, 0.75 and 0.95) as shown in Figure 1.

---

7 For example, when $OFI = 0.25$, and with $D_{3,jt} = 1$ (namely, the range of $IFI$ is between 0.2 and 0.3, and other dummies take a zero value), the simulated GDP per capita growth is $8.92904$ (i.e. $7.52687 + (-0.08675)\ln(0.25*100) + (0.522359)\ln(0.25*100) + 1$).
The first observation in Figure 1 is that economies with a higher performance in openness (with higher $OFI$) produced a higher level of per capita GDP growth at all levels of $IFI$ above 0.1. In economies with $IFI$ below the median, a higher performance in $OFI$ always produced a higher economic growth measured in GDP per capita, except when $IFI$ is below 0.1. The second observation is that, when the $IFI$ is above median, economic growth kept rising regardless of the performance in the $OFI$ until an economy’s $IFI$ reached the range of 0.7 and 0.8, beyond which the growth rate of GDP per capita declined. This suggests that the 0.7 to 0.8 range of the $IFI$ is the optimal level, and
economies will reach their highest possible growth rates given their OFI.

When the value of OFI lies between 0 and 1, the marginal contribution of IFI to the per capita GDP growth of an economy is positive if the value of IFI lies between 0 and the optimal level. When the value of IFI is above its optimal level, the marginal contribution of IFI to an economy's GDP per capita growth is negative. In short, if an economy has an IFI value below 0.1, a lower value of OFI actually produces a higher per capital GDP growth. So long as the value of IFI lies above 0.1, the marginal contribution by the different level of OFI to per capita GDP growth is positive. On the contrary, when IFI lies between 0 and 0.1, the marginal contribution of OFI to per capita GDP growth is negative.

The analysis can be extended to examine the marginal effect of both OFI and IFI. By plotting the change in the per capita GDP growth rate against the IFI at different level of the OFI, Figure 2 shows that, at different level of IFI, a higher OFI can lead to a larger change in growth rate of per capita GDP. However, as shown in Figure 3, the marginal effect of IFI on the change in growth rate of per capita GDP at different level of OFI is increasing at a decreasing rate. Furthermore, Figure 3 shows that when the OFI value is

---

8 This can also be seen if Equation (4) is modeled as a continuous or differentiable function, where 0 < i < 1, and IFI* represents the optimal value:

\[
\frac{\partial \ln y}{\partial \text{IFI}} \text{ for } 0 < \text{IFI} < \text{IFI}^*, \frac{\partial \ln y}{\partial \text{IFI}} > 0; \quad \frac{\partial \ln y}{\partial \text{IFI}} \text{ for } \text{IFI} > \text{IFI}^*, \frac{\partial \ln y}{\partial \text{IFI}} < 0.
\]

9 When the function is a differentiable, the results can be summarized as follows:

\[
\frac{\partial \ln y}{\partial \ln \text{OFF}} \text{ for } 0 < \text{IFI} < 1, \frac{\partial \ln y}{\partial \ln \text{OFF}} > 0; \quad \frac{\partial \ln y}{\partial \ln \text{OFF}} \text{ for } 1 < \text{IFI} < 0.5, \frac{\partial \ln y}{\partial \ln \text{OFF}} < 0.
\]

10 The marginal effect can be summarized as follows when a differentiable equation is used:

\[
\frac{\partial \ln y}{\partial \text{IFI}} \text{ for } \text{OFF} = 0.25, \frac{\partial \ln y}{\partial \text{IFI}} < \frac{\partial \ln y}{\partial \text{IFI}} \text{ for } \text{OFF} = 0.45, \frac{\partial \ln y}{\partial \text{IFI}} \text{ for } \text{OFF} = 0.65, \frac{\partial \ln y}{\partial \text{IFI}} > \frac{\partial \ln y}{\partial \text{IFI}} \text{ for } \text{OFF} = 0.95.
\]
below median, the marginal contribution of economic openness towards the economics growth is larger than that when OFI is above median.\textsuperscript{11}

![Figure 2 Marginal Effect of OFI on Growth](image)

\textsuperscript{11} The marginal effect can be summarized as follows when a differentiable equation is used:

\[
\frac{\partial \ln Y}{\partial \ln OFI \text{ Below Median}}_{\text{IFI}=\text{IFI}_1} > \frac{\partial \ln Y}{\partial \ln OFI \text{ Above Median}}_{\text{IFI}=\text{IFI}_1}
\]
With the construction of the two indicators that look separately at indigenous factors and openness factors, the regression and simulation results provided additional evidence to other studies (for example, Hesmati 2006) that indigenous factors can have independent influence on growth and openness. Various policy recommendations can then be suggested from the empirical and simulation analysis. Firstly, a more globalized economy indicated by the higher performance in economic openness does not always lead to higher economic growth; for those economies with $0 < IFI < 0.1$, they should improve on the $IFI$ in order to reap additional gain from openness and ultimately globalization. Secondly, economies whose $IFI$ is above 0.1, but below the optimal range (0.7 to 0.8), should aim to improve the performance of the indigenous factors, hoping gradually to reach the optimal level.

A pattern of relationship between economic growth, performance in the openness
factors and indigenous factors seems to have emerged from the simulation analysis. Figure 4 argues that once the performance in the indigenous factors has reached a minimum level, improvement in indigenous factors will lead to a larger per capita GDP growth rate at every higher level of openness. Thus, at a high level of openness, OFI3 for example, a higher level of per capita GDP growth rate can be achieved.

To see how the 62 world economies perform in the 1998-2002 period, Table 4 maps out the sample period average in five different ranges of OFI and IFI. Individual economies can consider their own positions in the ranking of the two indicators, and compare their performance with other economies, including the periodic average in the GDP per capita growth rates. There are seven mainly poor developing economies (Bangladesh, Indonesia, Kenya, Nigeria, Pakistan, Senegal and Uganda) that have the
lowest rankings in both indicators. On the contrary, those economies that performed strongly in both OFI and IFI are mainly developed economies (Austria, Denmark, Finland, Netherlands, Singapore, Sweden, Switzerland, United Kingdom and USA). Most developed economies have performed stronger in IFI than in OFI. Ireland is the only economy that has a stronger performance in OFI than in IFI in the sample period.12

The observation from Table 4 is that performance of indigenous factors is the more relevant constraint in the globalization process of any economy. Most economies that are strong in the performance of IFI are also strong in the performance of OFI, but not the reverse. In other words, it would be appropriate for economies to improve their indigenous conditions and environment before they can gain from openness and globalization. Economies have to achieve a reasonable level of performance in indigenous factors before gaining the benefits from openness factors. A good performance in indigenous factors is essential to openness, growth and development. There are a number of economies (Argentina, Botswana and so on) that have achieved a median in IFI, but showed low performance in OFI. The 0.61 to 0.80 range of the IFI seems to be the critical range, as virtually all industrially advanced economies achieved an IFI score above 0.61.

Table 4 shows that a number of economies in the second lowest (0.21 – 0.40) range of IFI experienced a relative high growth rate in the sample period. For example, China has a growth rate of 6.749 percent and the Russian Federation had 6.381 percent and so on. This suggested that these economies have to improve their IFI before reaping the

---

12 Measured in purchasing power parity constant 2000 price, Ireland’s GDP per capita is highest among the 62 world economies.
gain from openness and globalization. Among the developing economies, African economies (e.g. Uganda, Kenya and Senegal) are the weakest performers in both the OFI and IFI, while the middle-ranking economies are the few Asian (e.g. Thailand and Malaysia) and Latin American (e.g. Panama and Chile) economies. Other Asian economies (e.g. India, Indonesia, Philippines and Sri Lanka) performed poorly in both OFI and IFI. The group of developing economies that have reached the range of 0.61 – 0.80 in the IFI are mostly Eastern European economies (e.g. Hungary, Slovenia and Czech Republic), which will probably be the next group of countries that would benefit from globalization. The lesson is that sound performance in the various indigenous factors will facilitate good performance of openness factors. In short, advancement in the performance of indigenous factors will help promoting openness.

*Countries with $IFI<0.1$
V Conclusion

Recent globalization indices ranked the performance of different world economies with few or without the inclusion of domestic or indigenous factors (Anderson and Herbertsson 2005, Kearney 2005 and Dreher 2006). The empirical results in the paper add to the globalization debate and the construction of the globalization index by making reference separately to the relevance and importance of a number of indigenous factors.

In constructing the OFI, this paper takes into account the pattern of trade and industries by incorporating the inter-industry and intra-industry trade, in addition to the total trade flows. The number of indigenous factors used in the construction of IFI should provide a more comprehensive picture on the domestic performance of different economies. The regression result that indigenous factors are important in promoting an economy’s growth led to further investigation and analysis on the relationship between the two types of factors. Given different level of performance in the economy’s openness, a higher performance in the IFI will produce a higher growth rate. When the performance of an economy’s indigenous factors is extremely low, it would be more appropriate for that economy to improve its indigenous factors than to engage in globalization. In short, performance in the indigenous factors is the more fundamental issue than economic openness. Before the “optimal” level of indigenous factors performance is reached, the economy will get better off in per capita GDP as the performance of indigenous factors improve.

Literature on the gain from globalization points to the importance of a sound performance in domestic factors. By comparing the 62 world economies in their
performance in both the openness and indigenous factors, one comes to the conclusion that sound performance in the indigenous factors is very crucial to economic openness and globalization. All economies with strong performance in economic openness and globalization have sound performance in their indigenous factors. For those world economies that are ranked low in the IFI, appropriate economic policies should be conducted to improve the performance of different indigenous factors.
