Islamic home finance: legality, pricing, and profit - Models compared

Zubair Hasan

Professor of Islamic Economics and Finance

INCEIF: The Global University of Islamic Finance, Kuala Lumpur

Abstract

The Musharakah Mutanaqisah Partnership model or the MMP is fast gaining popularity in Islamic home financing, for jurists and the bankers both validate it as a totally interest free structure. We have exploded the myth of that validation in our earlier writings and reinforce our argument here. But on a more important side, we shall show that the construct, which some now refer to as the Zubair Diminishing Balance Model or the ZDBM, is cheaper for the customer without reducing in any way the profit margin for the bankers; Instead, it provides them with a competitive edge over their mainstream rivals at zero cost. The model is more efficient: it uses fewer resources, the rate of return on investment remaining unchanged. Liquidity in the system is improved and social cause is served as the price of a basic human need is lowered. In contrast, the MMP is complicated, implies compound interest in practice, and is prone to Shari'ah frowns. ZDBM is especially fairer in the treatment of default related issues. It also does not invite the tensions which rental determination/revision or property valuation creates in the MMP programs. In this context the paper refers as illustrations to actual cases from some countries where MMP is gaining ground. The innovation of charging on diminishing balance may usher in revolution in finance.

Key words: Islam; home finance; implicit interest; MMP model; ZDBM.

INTRODUCTION

It is gratifying to note that Muslim countries have of late been turning to the importance shelter has among the basic human needs which an Islamic order is obliged to meet for promoting communal peace and harmony; efforts are on the rise to bridging the yawning demand and supply gap in this vital area of civilized living. Islamic banks too have launched a number of schemes for home financing. Among them, they initially started with the structures based on the BBA but are recently shifting fast to *Musharakah Mutanaqisah Partnership* (MMP) models as replacement due to their apparent immunity from interest.

However, Hasan (2011) demonstrated that the conventional finance and the MMP are at par with regard to interest use and that the *Diminishing Balance Model* -- henceforth called the ZDBM -- is a better alternative. The proposed model is entirely free from juridical suspicions and has in principle already won affirmation from a few industry leaders of international repute. That paper compared the consequences of three alternative structures for home financing – the conventional, the MMP and the ZDBM – keeping the details of the case unchanged. It was shown that the results were identical for the conventional and the MMP models; the ZDBM being not only cheaper for the customer but at once interest-free and law abiding. The paper was presented recently at the monthly faculty seminar at INCEIF to elicit comments. Some doubts about the efficacy of the model to match the current

Islamic finance environ demands and modus operandi were voiced. The present revision seeks to clear those doubts and brings to light a few additional merits of the ZDBM.

THE QUERIES:

The main points raised at the seminar included the following.

1. The illustration uses six-monthly installments. In most home financing cases the contracts provide for monthly payments. The results arrived at might have been different if the installments payment were kept in the illustration of the same duration.
2. The illustration does not explain why or from where it takes 8% as the rate of return to derive its results. The ZDBM is apparently cheaper because the return does not cover the cost of capital as also the risk premium.
3. If the ZDBM is cheaper for the customer by the same token it is less profitable for the banks – why should the latter accept or implement it?
4. The installments in the ZDBM are not fixed, that may confuse the customer with reference to the payment schedule. Also, the payments in the model are larger in the beginning and could be harsh on the young home buyers: the scheme is not commensurate with the life-cycle income hypothesis at the theoretical plane.
5. Banks prefer faster return of their capital and it is faster in the MMP than in the ZDBM, banks would tend to shun the latter.
6. The MMP model deployment in Malaysia is different than in other countries, a local case must have been included in the study if its claims are to carry conviction in this country.

To me, the first two of these comments hold little water. The exercise was purely illustrative meant to bring out the model differences. Using common data was a methodological imperative not an expression of ground reality and its complications¹. Whatever benchmarking the industry is using in other cases may be used for deciding the mark-up in the ZDBM. Comment three ignores the common experience that cheaper things sell more and faster. ZDBM lends the Islamic banks a much needed competitive edge in the market: what they would lose on the swings more than that they must gain on the rounds. Whether the installment amount is fixed or continually falls as in the ZDBM makes little difference to the customer as he would have the schedule of installment known before he signs the contract. Anyway, we shall revert to this objection later in the discussion Banks

¹ Incidentally, one may note that in MMP “the rent is calculated based on 1 year LIBOR. The floor rate (minimum rate) and the ceiling rate (maximum rate) are stated based on which the rentals rate can vary. In agreement, it is stated that if payment is made on time, the transfer of ownership will take place accordingly” (Shaikh 2011).

do prefer faster return of their capital but the claim that recovery is faster in the MMP compared with the ZDBM is, we shall see, contrary to the facts.

The demand for inclusion of the Malaysian case is doubtless weighty and genuine. We could not lay hand on a numerical illustration as to how an Islamic bank in Malaysia determines the rental or the installment amount for home financing contracts. In our search the easiest was to look for an explanation of the Malaysian MMP operations in Rosly (2010, pp.141-143) the Head of the Banking Department at INCEIF. The reference did not simply contain the needed information: the book does not explain or illustrate as to how the amount of installment is fixed in Malaysia or elsewhere. Instead, the chapter raises a number of queries without answering any. An internet search however provided scour. The available information though not sufficiently revealing did show that even as the banks use different rental rates - fixed, floating or mixed - in home financing contracts in the Malaysian usage of MMP, the *technical* procedure of rental rate adjustment to arrive at the installment payments is the same². The MayBank announcement, the ISRA paper, ‘Shaping Islamic Finance together - Malaysia’ Home page plus the write up of Osmani & Abdullah (2010) were reassuring.

In any case, the fixed rental usage remains on the table in Malaysia as well. If the amount of investment and frequency of installments is known a redemption factor is added to the rental to so fix the periodic Installment that the future incoming money flows may be discounted back to the current value of investment. This is the standard amortization technique used by conventional interest financing. Calculators are programmed to help customers find out for themselves the installment amount by feeding the relevant data into the system. One such calculator is available at the Kuwait Finance House web page.

AN ILLUSTRATION

One illustration of this sort of amortization process is available at the web page of LARIBA the Islamic finance arm of the celebrated American Finance House; The “Lease to Purchase model” or LTP of the bank is typical of the MMP deployment in the home financing area. To explain the LTP application process the AFH takes in their illustration the cost of home as \$150,000. The

² The MMP agreement of HSBC Amanah uses in their MMP home financing the standard mainstream formula $A = PV_m / 1 - (1 + r_m)^{-n}$ for for discounting back the future stream of cash flows to their present monthly value A, given the present value of the flows PVm, r the monthly rate of return and the time frame n. Palpably the formula operates through a compounding of interest principle

client pays \$30,000 as down payment while the remaining \$120,000 is provided by the LARIBA. The property is purchased jointly by the parties. The deferred payment is to be cleared over 15 years; the transaction involves an implicit interest rate (p.3)³. What this rate is they do not indicate in the document. However, it is not difficult to find its magnitude from the data they provide in their Table 1 as reproduced below.

Table 1: Amortization scheme under the LARIBA LTP Model

Month	Return on capital	Return of capital	Payments	Balance
Beginning	---	---	---	\$120,000
1	\$800	\$347	\$1147	\$119653
2	\$798	\$349	\$1147	\$119304
3	\$796	\$351	\$1147	119054
---	---	---	---	---
179	\$6	\$1141	\$1147	870
180	\$7	\$1140	\$1147	\$0
Total	86460	120000	206460	
Rate of return = 86460 / 15 = 5764. (5764/120000)100 = 4.82%				

The rental being \$1000 a month, the annual return on \$150,000 will be 8% (interestingly, the same as in our example). Now, if we assume the capital redemption factor added to this rental as B, we have:

$$(0.08 + B) 120,000 = 1147 \times 12 \quad (\$1147 \text{ is the monthly installment}) \dots \dots (1)$$

$$\text{This yields } 9600 + 120,000B = 13764 \dots \dots \dots (2)$$

$$\text{Therefore, } B = [13764 - 9600] / 120,000 = 0.0347 \text{ or } 3.47 \% \dots \dots \dots (3)$$

Thus, 3.47% is what the AFH document refers to as the imputed or implied interest we noted above. It is easy to verify the result. Putting B = .0347 in equation (1) we get the monthly installment = \$1147, the same as in Table 1⁴. Thus, there is riba in the home financing program of the LARIBA. Still, the AFH claims and extensively publishes the world over that their model is at once *Shari'ah* compliant!

³ This disclosure had to be made in compliance with the requirements of the financial law in the US.

⁴ Note that we have calculated the entire data for the Table as included in the Appendix. To do that we have derived two formulae given below---(i) $K_n = \beta K_{n-1} - I$, Where K_n = Outstanding balance at nth installment number, I = Installment amount $\beta = (1+R/A)$ where R = Monthly rent and A = initial value of the house. (ii) $r = [I - (R/A)K_n]$ where r = capital return component in the nth installment.

They nicely rap up interest in a rather foxy language as to how the return on capital is determined. Conventional banks straight away tell the customer that the quoted interest rate is not sufficient to fix the installment amount that would redeem his liability to the bank on the stipulated date unless an appropriate redemption factor is added to the rate⁵. But the LARIBA document states that the *total* monthly charge containing return of capital plus the return on it would be a fixed amount depending on the payment plan data – the agreed rental, number of installments and the initial contribution of the parties to acquire joint ownership of the house. The implicit addition of a redemption factor is not mentioned. This is happening even as AFH has the cream of world jurists at their advisory let by Sheikh Taqi Usmani who append their signatures to the document. Possibly the learned Jurists could not look into the mathematics of the model. In substance the position is presumably no different in Malaysia.

Of course, there usually is a provision in the MMP to review the rental rates for a change with mutual consent of the contracting parties especially if it is a long duration deal. But that does not alter the underlying amortization principle used with an in-built interest factor. The contract can be having time tranches using different rentals but the amortization process used for fixation of installments for a tranche remains unchanged. Meera and Razak (2009 Sections 3.1 and 3.2) have candidly demonstrated the fact using both (a) flexible rentals and (b) flexible property prices. Banks in Malaysia tend to tie the rental with movements in the BLR/BFR to impart what they call *flexibility* to the rental under the MMP.

Let us now explain the *Diminishing Balance Model* (ZDBM) and show its working using the same LARIBA illustration. Assume that the bank proposes to the client as follows. You have already paid \$ 30000 to the seller as earnest money. The remaining \$ 120000 the bank shall pay for acquiring the co- ownership in the house, you acting as our agent. For getting back the amount in 180 monthly installments over a period of 15 year, we shall put a yearly mark-up of 8% on our share in the cost of the house. However, the mark-up amount will be reduced proportionate to the return of our money. That would help reduce your liability to the bank. The registration of the house in the court will be in your name but you will have to sign a mortgage deed pledging the property with the bank as security until installments as per Table 2 have all been cleared in full. The Table provides the calculation for your monthly installments.

The return on capital portion in the installment is calculated at an agreed annual mark-up of 8% per annum operating on the diminishing balance. Thus, the installment would have a fixed

⁵ In fact conventional banks add an appropriate redemption factor to the interest rate to ensure that the discounted income stream that installment payments generate equals to the present value (PV) of the loan. The jurists have to clarify the reason of allowing it in the MMP contracts as it imparts an interest element to the agreed upon rental rate

component of capital return amounting \$ 666.67. The return on capital will be calculated on the capital remaining outstanding at the beginning of each month at $.08 / 12 = 0.00667$ or 0.667%. The return on capital RoC for any installment n can easily be found using the following formula

$$RoC_{(n)} = [A - (n-1) C] r$$

Where n is the required installment number

A is the initial payable amount

C is the fixed capital component of the installment and

r is the monthly mark-up

= \$ 13.32 the same as in Table 2.

Table 2: Working of the Diminishing Balance Model

Installments Number n	Return of capital B	Diminishing balance C	Mark-up amount D	Installment Payments E = B + D
0	---	120000	---	---
1	666.67	119333.33	799.20	1465.87
2	666.67	118666.66	794.76	1461.43
3	666.67	117999.99	790.32	1456.99
---	---	---	---	---
178	666.67	1999.41	13.32	679.99
179	666.67	1332.74	8.88	675.55
180	666.67	666.07	4.44	671.11
Total	120000	---	72395	192328

$$\text{Rate of return} = (72395/15 = 4826. (4826/120000)100 = 4.02\%$$

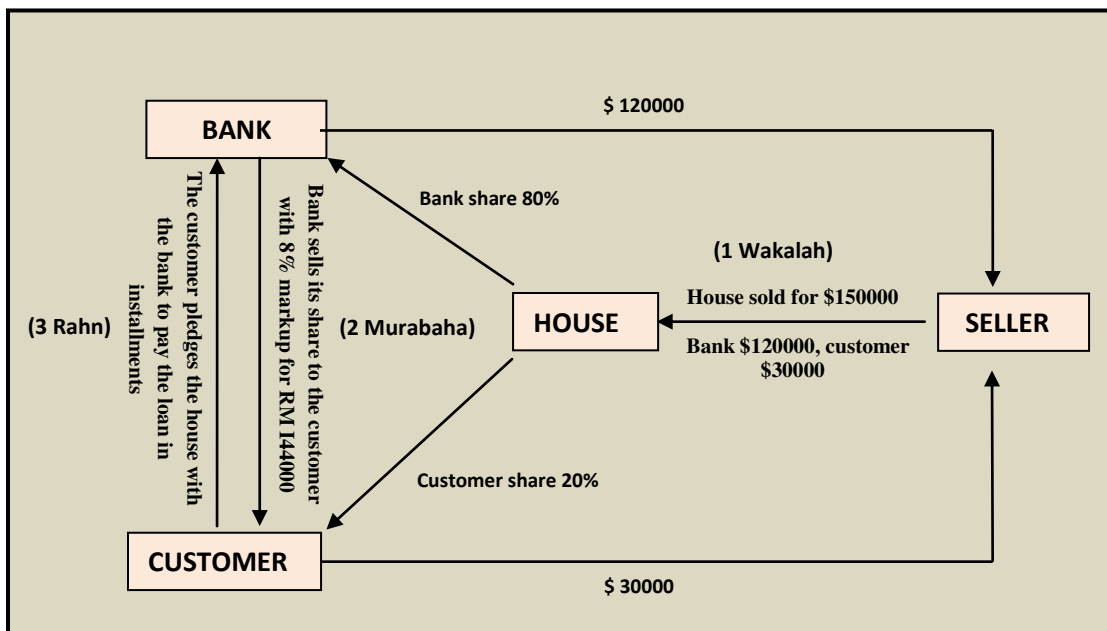

Figure 1: Diminishing Balance Model in operation: Three independent contracts

For example the return on capital for installment number 178, we can get it as under.

$$\text{RoC}_{(178)} = [120,000 - (178 - 1) 666.67] \cdot 0.00667 = 13.32$$

If we add to this amount the capital component 666.67 we get Installment 178 = \$ 679.99.

Notice that three separate contracts are involved in completing the sale-payment process under the ZDBM program.

1. First is a contract of sale for joint ownership of the house involving three parties: the bank, the customer and the seller. The customer agrees to treat the earnest money as paid for both the partners. The seller sells the property to the co-ownership of the bank and the customer after the former pays the balance of \$ 120000 to him to acquire an 80% share in the house.
2. Second is the contract between the customer and the bank, the latter selling his share in the property to him with an agreed mark-up spread at 8% a year on the outstanding amount.
3. Third is the contract whereby the customer mortgages the house with the bank until the payments are all cleared in accordance with the terms of the mortgage.

The three contracts are to be executed consecutively. The house is to be registered in the name of the customer. The customer would have to pay as return *on* capital (RonC) to the bank in both MMP and the ZDBM additional to the return *of* capital (RofC) component in the installments. The calculation of the de facto rate of return on capital is shown in the Tables above. In each case the total return is first divided by 15 the number of years involved. The result is then used to calculate the rate of return on capital \$120000. It can be seen that in the MMP structure the customer has to pay a higher rate (4.8%) than under the ZDBM (4.02%). The gain of 0.8% a year i.e. \$80 each month in substantial payments will be welcome to anyone – a cool \$14400 saving over the contract period. This gain would increase with shortening of period or converting monthly installments to yearly ones, other things remaining unchanged.

CAPITAL COST RISK COVERAGE AND RELATED ISSUES

Critics argue that the ZDBM is cheaper because it ignores capital costs and risk premium which elements are taken care of in the MMP model by adding a redemption factor to the base rental. Let us not raise here the ticklish issue as to how this component is measured and how logical is its basis. Granted for the moment that its determination is not arbitrary and quantum unfair, it is interesting to note that the ZDBM without in any way reducing the margin of profit for the bank.

It is cheaper because it reduces the funding deposits of the bank proportionate to the reduction in profit thus leaving the margin unchanged.

$$\text{Price} = \text{cost of funds} + \text{risk factor} + \text{hurdle costs} + \text{overhead costs}$$

Cost of funds includes deposit cost, statutory reserve ratio (SRR) and liquidity requirement (LAR) cost. Risk factor includes cost of capital charge to absorb market, credit and operational risk. Hurdle rate is the return the bank expects to earn.

Since objective of this brief note is restricted to showing that under the ZDBM deployment, the bank's rate of return on capital investment remains unaffected, we have assumed that deposits match with financing amortization balance. SRR is taken at 4% with zero return and LAR at 2% on 1% minimal return. Capital charge is calculated at 4% equaling half of the 8% mark-up the bank uses. Hurdle rate and overheads are ignored to keep the matters simple. For demonstration we are using the same illustrative case of LARIBA as we used in the earlier paper.

The indicated rates in column headings being annual have been divided by 12 in each case to calculate monthly figures. The excerpts from relevant Excel worksheets are produced below for both the ZDBM and MMP cases to show that the de facto rate of return in the two models are the same. The Tables also narrate the happenings on both the assets and liabilities sides of a bank's balance sheet. **Notice also that the return on investment is identical at 4.82% (0.41 x 12) in the two models (Column 12).** However, the *funding deposits* are much lower in the ZDBM – about 20% less than the MMP. Thus, ZDBM is more efficient than the MMP in matters of fund utilization and possibly in granting liquidity.

Table 1: ZDBM is cheaper for the customer without being costlier to the bank

Months	Exposure structure (Assets side)						Risk coverage (Liabilities side)				Margins

Total	13724502									56689.82			
Mean	76247												

The exercise above may not be very sophisticated but I believe it does clinch the claim under discussion. The chart below makes the case clearer. One can easily see that the funds commitment curve for the MMP has a marked bulge which is both the effect and evidence of the usage of compound interest formula in the installment determination. The ZDBM follows the straight (line) path.

Figure 2

A related claim is that return of capital in MMP is faster compared with the ZDBM. This too defies facts. The rent in MMP is shared in the capital contribution ratio of the parties which remains higher for the bank for quite some time thus giving it a larger chunk of rent in the fixed

installment relative to the capital return component in it. In contrast, the capital recovery component in the ZDBM is fixed; the installment tapers off due to the bank share in the rental from the high to low values. Figure 3 based on data in the Appendix helps clarify the position. It is clear that until month 93 the return of capital remains higher in the ZDBM. It is uniform through out. In the MMP recovery is much slower in the initial stages but climbs up at an increasing rate becoming higher and higher after the mid-way is crossed.

Figure 3: Return of capital is higher under the ZDBM until the 98th month

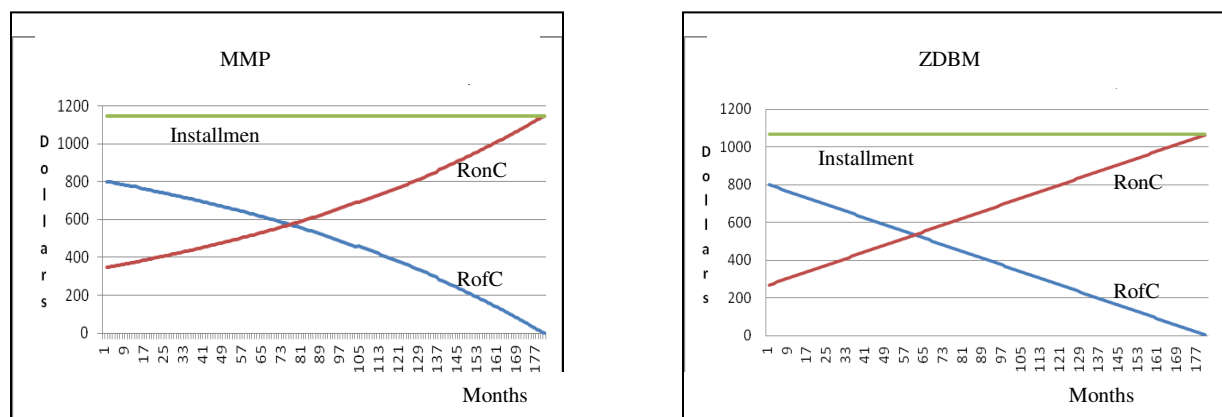

Finally, it is argued that the addition of what is called the redemption factor to the interest/rental rates in the conventional/MMP models has the advantage of keeping installments uniform over the contract period which may have some psychological value for the customer. But firstly a bank offering ZDBM can explain to the customer that installment payments will be known to him in advance from the schedule attached to the contract. Secondly, if one still insists on uniformity of

Table 3: working with uniform installments

Installments Number	Return of capital B	Diminishing balance C	Mark-up amount D	Installment Payments E = B + D
n	B	C	D	E = B + D
0	---	120000	---	---
1	269.25	119333.33	799.20	1068.45
2	273.73	1118666.66	794.76	1068.45

---	---	---	---	---
178	1055.13	1999.41	13.32	1068.45
179	1059.57	1332.74	8.88	1068.45
180	1064.01	666.07	4.44	1068.45
Total	120000	---	72395	192328

Rate of return = $(73327/15 = 4826. (4826/120000)100 = 4.02\%$

installments as indeed crucial one can make them uniform under the ZDBM as well. We may divide the total payment on capital and income accounts under the ZDBM by the number of installments to obtain uniformity. From the uniform installments so obtained we deduct the monthly income to find the capital component column./ We reproduce the data of Table 2 after necessary adjustments in Table 3. The exercise of making the varying installments uniform in the DBM in fact brings to focusing on a few more merits of the structure compared to the MMP. Consider the set of diagrams in Figure 4. They help highlight some more features of the model.

A **Figure 4 Uniform Installments and their components** **B**

in addition to its relative cheapness. RonC crosses the RofC earlier in the model than in the MMP. It means that the outstanding debt on a default date after that point would be smaller in the ZDBM model. The Appendix reveals that until month 77 the bank receives \$34670 as return of capital under MMP and the remaining \$52802 as return on it out of the total installment payment of \$ 87172. Bank preference is clear; its position strengthens in a situation of default. To illustrate, suppose the default occurs in the 77th month itself. Over 70% debt in MMP is still outstanding, while the customer has paid almost 46% of the return on capital the bank would eventually get under the contract in 42% of the time. Is this a fair and equitable situation from the individual or societal view point? On the other hand, under the ZDBM the return of capital is pro rata – 42% returned in equal time and to the advantage of the bank. Finally, the non-linearity of the curves in MMP unveils the compounding element in the variables. The linear functions in the ZDBM confirm its absence.

CONCLUDING REMARKS

This paper reinforces the argument of my earlier writings that the MMP model for Islamic home financing is no better than its conventional counterpart in *riba* usage or its consequences for the

participants in the program.⁶ The amortization exercise in these contracts uses not only interest but the rates invariably follow a compounding pattern, something even more severely condemned in the Quran. How Islamic jurists could stamp such agreements as Shari'ah compliant just beats me. It may be argued that MMP uses interest rate just as a bench mark. But for that reason the result of the model should be different if rate of interest on home finance and the rental are identical. Unfortunately, that is not the case. I trust Islamic bankers would take note of the *Diminishing Balance model* - the ZDBM. It is at once Shari'ah abiding and cheaper for the customer. Also, it avoids all the complexities of the rent or property value revision that confront us in the MMP. The relatively larger installments in early stages in the ZDBM may be a boon not a bane for younger people who may not have started the family yet or may be having fewer small kids. The life cycle income hypothesis need not haunt us; it is a tiny ghost, if at all.

In fact the model enunciates a general principle and procedure, home finance taken as an illustration. Once this principle and procedure are accorded recognition by the industry, Islamic finance modes are likely to undergo some radical and gainful transformation giving a much needed competitive edge to the system over the conventional in every sphere of economic activity. Malaysia can add another shining feather to its leadership cap in Islamic finance.

ACKNOWLEDGEMENTS

The author expresses his deep gratitude to all those who sent in their comments on the earlier versions of this paper. Among them, I would like to mention the names of the former and the current PCEOs of INCEIF Mr. Agil Natt and Mr. Daud Vicary Abdullah respectively, both counted among the leading lights of the banking industry at the global level. Mr. Daud wrote about the Diminishing Balance Model or the ZDBM for Islamic home financing on the INCEIF Blog - *Diamonds in the cupboard* - on August 22, 2011 as follows

As a former practitioner I found the content not only fascinating, but also the relevance of the ZDBM structure for reducing the cost of Home Financing to the customer. I would strongly recommend that my colleagues in the profession and Islamic Finance customers alike to take a look at this innovative product and see how it can be implemented for the benefit of all as soon as possible.

Thanks are also due to Nurhafiza Abdul Kader Malim, and med Ashraf bin Mohamed Iqbal, going through a few earlier drafts for error removal, the latter making some valuable suggestions for strengthening the argument. Roslan Ahmad deserves special mention for his valuable contribution on product pricing.

⁶ The situation in Malaysia is unclear. Most banks using the MMP facility do not publish unlike LARIBA the working of their models. The agreement pro forma does not explain the juridical aspect of the contract. Explanatory worksheets are not available. On the other hand, the documents hardly miss any clause to widen the discretionary powers of the banks. Even the daily receivable profit is calculated in some cases to better inform the customer – one is prompted to ask: is profit interest? It is time that the regulators lay down the minimum what the banks must reveal and cannot insert in their standard agreement forms. At present, vagueness to the bank advantage is their hallmark.
