A DEA approach to regional development

By

George Emm. Halkos and Nickolaos G. Tzeremes

Department of Economics, University of Thessaly Argonavton and Filellinon st., 38221, Volos, Greece

Abstract

Our research is based on the effect of fiscal policies on the Greek prefectures. Using DEA methodology we compare the efficiency of the prefectures over the last three decades. Moreover, we determine where the resources are distributed in an efficient way and /or have been used efficiently by the local authorities in order to stimulate regional development and provide quality of life to the Greek citizens. The efficient prefectures seem to have definite and strong characteristics, which are determined and discussed in detail. Our empirical results imply that the resources of a prefecture don't necessarily ensure the efficiency of this prefecture.

JEL Classification Codes: O18, P25

Keywords: Data Envelopment Analysis; Regional Development; Living Standards; Greek Prefectures

1. Introduction

It is generally accepted that the level of economic development is not uniform across regions. On the contrary, it substantially differs. This plays an important role and stimulates internal migrations from less developed prefectures too more developed ones. As human activities are related to economic development and are affected by regional development, the way of measurement of the conditions of regional development is really essential and important in the determination of a country's socio-economic policies.

In many countries, governments have tried to establish policies able to reduce regional economic discrepancies. Georgiou (1992) and Karkazis and Thanassoulis (1998) assess the effectiveness of regional development policies of the Greek Governments. Greece used the Development Act 1262 of 1982 in order to make the differentiations and disparities in economic development more uniform. The main target behind those policies was the economic development of the prefectures with a direct impact on the citizens' living standards. In the case of Greece different policies and implications for economic development of the prefectures have been observed, due to the entrance of Greece into the European Union.

Similar policies can be found in other countries like Italy (facing migration moves from South to North parts of the country) and the UK. Mishan (1988) assesses the performance of public expenditure policies using cost-benefit analysis (CBA). Meen and Andrew (2004) analysed the impact of fiscal policies on UK's regional development from the perspective of population distribution. In a similar way, Newton (1972) applied CBA to assess the performance of specific types of public investment on a regional basis. But CBA due to its additive nature limits its ability in measuring performance on a comparative basis, as we are interested in the benefits relative to costs and not to the absolute net benefits. In this paper a non-parametric analytic technique for the evaluation of prefectures' performance is applied. Specifically, the Data Envelopment Analysis (hereafter DEA) technique is employed, which is a non-statistical method relying on linear programming. It provides a measure of relative technical efficiency of different decision-making units (hereafter DMUs) operating and performing in the same or similar tasks. The technique's main advantage is that it can deal with the case of multiple inputs and outputs as well as factors, which are not controlled by individual management.

Another advantage of this non-parametric technique, and in general of all the nonparametric techniques, is that we skip most of the usual difficulties, which arise by the use of parametric methods in the analysis of ratios. That is, we skip problems like the necessity to determine the functional form¹ or to determine the statistical distribution of the ratios. Additionally, when we refer to the analysis of ratios problems arise if the numerator or the denominator takes negative values, while the manipulation of outliers is not clear. On the contrary, using the proposed technique these difficulties can be overcome and the most efficient prefectures can be found in relation to the empirical data in use. Then the less efficient prefectures can be compared to the most efficient ones.

Thus, in this study applying DEA to the Greek prefectures, we obtain the efficiency scores and the optimal output (ratios) levels for inefficient prefectures for the last three decades (1980, 1990, 2000). For the first time, we use a number of inputs and outputs in a DEA framework formulation seeking efficiency comparisons with the simultaneous use of multiple criteria, which determine efficiency for each DMU, forming a rounded judgment on DMU efficiency taking into consideration a variety of efficiency dimensions and combining them into a single performance measure.

Specifically, DEA provides us with an overall objective numerical score, ranking, and efficiency potential improvement targets for each one of the inefficient units. The comparison of relative efficiency of all prefectures is carried out, relying on the derived efficiency ratio for every prefecture, as the solution of the mathematical model. The higher a prefecture's efficiency ratio in relation to the corresponding ratio of another prefecture the higher is the efficiency of this prefecture.

This paper is organized a follows. Section 2 presents a review of the existing literature. In section 3 the various variables that are used in the formulation of the proposed model are presented and discussed. In section 4 the technique adopted both in its theoretical and mathematical formulation is presented. In section 5 the empirical findings of our study are obtained. The final section concludes the paper discussing the derived results and the implied policy implications.

2. Literature Review

DEA is a very important tool for analysing efficiency gains and provides a way for multidimensional measure. Charnes et al. (1989, 1994) have developed DEA models analysing the efficiency in terms of economic development of 28 Chinese cities. An extensive use of the models provided by Charnes et al. (1989) can be found in Sueyashi (1992) and Macmillan (1986, 1987) who measured the regional economic planning in the USA. Byrnes and Storbeck (2000) applied a multi-unit DEA analysis to regional economic development policy to Chinese cities. They used the data from Charnes et al. (1989), but in their model they had one output (value of gross industrial output) and two inputs (size of labour force and level of investment/ capital) recorded for the years 1983 and 1984. Moreover, in their study they measure the efficiency of the city with different types of measurement models introduced by Färe and Primont (1984). All of these studies were output based DEA models with variable returns.

Karkazis and Thanassoulis (1998) measured the effectiveness of policies for economic development in terms of private investment in Northern Greece. They used an output based DEA model with variable returns to scale and data for five years 1987-1991 with two inputs (public investments and investment incentives) and one output (private investment into service industry and agriculture). Chang et al. (1995) used DEA combined with Malmquist productivity index approach expressed by Färe et al. (1992). They evaluated the change of regional development in Taiwan area using indicators² for two years (1983 and 1990). They found that the larger the value of their indicators, the greater was the degree of development in that region.

Zhu (2001) used similar indicators for 15 US domestic cities and 5 international cities in order to demonstrate how DEA can be used for measuring the quality of life. Highand low-end housing monthly rental, cost of loaf of French bread, cost of martini, class A office rental (US \$ / ft^2) and number of violent crimes were used as inputs while median household income, number of population with bachelor's degree, number of doctors, number of museums, number of libraries and number of 18-hole golf courses were used as outputs. The purpose was to measure the quality of life across cities using the CCR model (Charnes et al., 1978). Without a priori knowledge of factor relationship, a multi dimensional quality of life measure was demonstrated.

Other approaches measure living standards by several economic development indexes (Quality of Life indexes) by satisfying a set of parameters. By using GDP and other indicators such as life expectancy and literacy rates economists have developed a methodology based on a technical literature measuring QOL (Atkinson and Bourguignon 1982, Dasgupta 1988, Kakwani 1993, Dowrick et al. 1998, Dowrick et al. 2003, Ditlevsen 2004). However this methodology has been criticised due to the fact that indexes most of the time don't have multidimensionality, thus an ideal index does not exist. The advantage deploying DEA methodology is exactly the fact that it measures multidimensional relationships among several inputs and outputs without an a priori underlying functional form assumption (Zhu 2001).

Previous research on efficiency and productivity of municipalities consists of studies which vary widely in their results and methodologies adopted. A number of studies, close related to ours, has been expressed, amongst others, by Weber and Domazlicky (1999), De Borger and Kerstens (1996), De Borger et al. (1994), Hayes and Chang (1990), Deller (1992), Domazlicky and Webber (1997) and Raab and Lichty (2002). DEA has the advantage of evaluating municipalities' efficiencies as well as their determinants. Most of the studies lack explanation of the estimated inefficiencies in a more systematic way (De Borger et al., 1994).

Domazlicky and Webber (1997) measured the growth rate of total factor productivity for forty-eight US states. Using public and private outputs and private and public sectors labor and capital as inputs, they constructed a Malmquist productivity index, which then was decomposed to changes of technical and scale efficiency as well as technological change. They found that the innovative states tended to use more private and less public capital, and less public labor compared to non-innovative firms.

Moreover, Raab and Lighty (2002) based on the identification of three distinct subregions comprising a metropolitan area, emphasize the role of the central urban core in regional economic development through stronger development initiatives between the core and its surrounding areas. Instead of explaining urban growth through cross metropolitan comparisons they explained it through intra-regional transactions. Furthermore, using a DEA additive model, with five inputs (employee compensation, proprietor's income, other proprietary income, indirect business taxes and intermediate imports) and four outputs (household consumption, business investment, government spending and exports) they tested the efficiency levels of counties both within and outside of the urban core. They found support indicating that core counties showed greatest levels of robust efficiency when applying DEA analysis and efficiency drops along with decreasing population densities and income levels as research moves away from the urban core.

Huges and Edwards (2000) using county-level data, tried to capture interjurisdictional spillover effects. Using the total property value as an output and fiscal policy as an input (expressed by government expenditure on education, social services, transportation etc.), they evaluated the efficiency of government performance using DEA. They noticed that larger land area tend to be less efficient, probably as a result of diseconomies of scale. This implies that decentralization and decreased spending by the public sector increase efficiency.

Our, work is among these lines using inputs and outputs, which are fundamental elements of regional development as well as of quality of life. Next the data used and the proposed methodology are presented.

3. Data

The implementation of uniform regional development needs an enormous amount of money and most of all the most effective use of resources. This, in turn, requires the knowledge of the relative conditions of the regional development of each area before we proceed to a long run sustainable planning. Information on indices of urban and regional development such as population density, urban planned area as a percentage of total area, number of telephone lines per 1000 people, number of doctors per 1000 people, average income per capita etc is substantial in formulating the regional development plans (Council for Planning and Development, 1990). The knowledge of this information helps authorities to understand the conditions of each area and plan accordingly its development.

The various indicators of each region differ as one indicator may be high and another may be low. This implies that it is important to weight the various indicators in order to obtain an indicator, which will help us to understand the current conditions of the regional development of each area. The main issue is how to weight these indicators in a realistic and representative way.

The National Statistical Service of Greece has recorded the data used here. They refer to the Census of the last three decades (1980, 1990, and 2000) for all Greek prefectures (see Fig. 1a). For the purpose of the analysis we code each of the 51 prefectures as shown in Table 1. This table also provides information on key characteristics of the prefecture (population, area in km², area in miles²). These prefectures form thirteen administrative regions, whose basic characteristics are also presented in Table 1.

For our research we use four inputs: 1) Number of hospital beds per 1000 citizens (**NHO**), 2) Number of doctors per 1000 citizens (**NDO**), 3) Number of public schools per 1000 students (**NPUS**), 4) Number of public busses per 1000 citizens (**NPB**) and three outputs: 1) GDP as a percentage of the mean GDP of the country (**GDP**), 2) Difference of urban rural population (**DUR**) and 3) Number of new Houses per 1000 citizens (**NNH**).

These variables have been used, measured and criticised by several economists in order to formulate, analyse and explain quality of life and economic/regional development³. Correlations and descriptive statistics are also presented in tables 2-3. The indicators can be categorized into four main areas: *Health (NHO, NDO), Education (NPUS), Living Standards (NPB, DUR, NNH) and Economic and Regional Development (GDP).*

Figure 1: Maps of Greece and Greek prefectures illustrating efficient prefectures per decade, according to their efficient scores.

4. The Technique

We may think of DEA as measuring the technical efficiency of a given prefecture by calculating an efficiency ratio equal to a weighted sum of outputs over a weighted sum of inputs. For each DMU these weights are derived by solving an optimization problem which involves the maximization of the efficiency ratio for that DMU subject to the constraint that the equivalent ratios for every DMU in the set is less than or equal to 1.

That is, DEA seeks to determine which of the N DMUs determine an envelopment surface or an efficient frontier. DMUs lying on the surface are deemed efficient, while DMUs that do not lie on the frontier are termed inefficient, and the analysis provides a measure of their relative efficiency. As mentioned, the solution of the model dictates the solution of (N) linear programming problems, one for each DMU. It provides us with an efficiency measure for each DMU and shows by how much each of a DMU's ratios should be improved if it were to perform at the same level as the best performing prefectures in the sample. In this way we extract an efficiency ratio for each prefecture, which shows us by how much the ratios of each prefecture could be improved so as to reach the same level of efficiency with that of the most efficient prefectures in the sample.

The fundamental feature of DEA is that technical efficiency score of each DMU depends on the performance of the sample of which it forms a part. This means that DEA produces relative, rather than absolute, measures of technical efficiency for each DMU under consideration. DEA evaluates a DMU as technically efficient if it has the best ratio of any output to any input and this shows the significance of the outputs/inputs taken under consideration.

4.1 DEA models (CRS vs VRS)

Under the restriction of Constant Returns to Scale (hereafter CRS), Charnes et al. (1978) specify the linear programming problem representing the fitting of an efficient

production surface to the data. An extension allowing for Variable Returns to Scale (hereafter VRS) is provided by Banker et al. (1984). The latter assumption requires an additional constraint on the solution, compared with the constant returns to scale case and the resulting efficiency estimate will be greater than that obtained under constant returns to scale. Thus, where the methods yield different values, the index obtained under variable returns takes account of scale related effects and therefore represents pure technical efficiency alone, whereas the constant returns to scale measure represents overall technical efficiency, in which pure technical and scale efficiency are combined.

Banker et al. (1984) show that the index of overall efficiency is equal to the product of the scale and pure technical efficiency indices. Hence, an index of scale efficiency can be obtained by manipulating the DEA results obtained under the assumption of constant and variable returns. Moreover, following Banker (1984), a measure of the local returns to scale properties of the technology can be obtained by aggregating the weights applied to the peer DMUs in constructing the hypothetical DMU used in the calculation of overall efficiency. Given the assumption of constant returns to scale (CRS), the size of the prefecture is not considered to be relevant in assessing its efficiency. Under the assumption of constant returns to scale (CRS) introduced by Charnes et al. (1978) small prefectures (in terms of population), can produce outputs with the same ratios of input to output, as can larger prefectures. This is because the assumption implies that there are no economies (or diseconomies) of scale present, so doubling all inputs will generally lead to a doubling in all outputs.

However, this assumption may be inappropriate for regional development and policy implications on quality of life amongst the Greek prefectures, because economies of scale (or increasing returns to scale, IRS) may exist. Based on this assumption doubling all inputs should lead to more than a doubling of output in terms or higher rates of regional development. For other prefectures, might become too large (in terms of population and absorption of resources) and diseconomies of scale (decreasing returns to scale, DRS) could set in. In this case, a doubling of all inputs will lead to less than doubling of outputs. It would be to the local administrations' advantage to ensure that its development (through the efficient use of the resources) is of optimal size -neither too small if there are increasing returns nor too large if there are decreasing returns to scale.

4.2 Advantages and limitations of DEA methodology

DEA modelling can incorporate multiple inputs and outputs. In order to calculate technical efficiency, information on output and input is required. This makes it particularly suitable for analysing the efficiency of fiscal policies on regional development. Possible sources of inefficiency can be determined as well as efficiency levels. The technique, gives the ability to decompose economic inefficiency into technical and allocative inefficiency. Furthermore, it allows technical inefficiency to be decomposed into scale effects. By identifying the 'peers' for the prefectures, which are not efficient, DEA provides a set of potential role models that the policy makers of the prefectures can look at, for ways of improving the effect of their fiscal policies on regional development and quality of life.

However, some major disadvantages when using this technique have to be mentioned. Having a deterministic nature DEA produces results that are particularly sensitive to measurement error. If one prefecture's inputs are understated or its outputs overstated, then that prefecture can distort the shape of the frontier and reduce the efficiency scores of nearby prefectures. It only measures efficiency relative to best practice within the particular sample. Thus, it is not meaningful to compare the scores between two different studies because differences in best practice between the samples are unknown.

DEA scores are sensitive to input and output specification and the size of the sample. There are different rules as to what the minimum number of prefectures in the

sample should be; one rule is that the number of prefectures in the sample should be at least three times greater that the sum of the number of outputs and inputs included in the specification (Nunamaker, 1985). Despite the limitations, DEA is a useful tool for evaluating the effect of policies on regional development and quality of life amongst the Greek prefectures.

4.3 Mathematical formulation

Let us now consider the problem diagrammatically. Assume that we examine the efficiency of eight prefectures ($C_1, C_2, ..., C_8$). To simplify things, we use two efficiency ratios: (a) GDP as a percentage of the mean GDP of the country and (b) the difference of urban rural population. Suppose that prefectures that achieve the optimal efficiency are C_1 , C_2 , C_3 and C_4 . The efficient frontier is determined from the segments that pass through points C_1, C_2, C_3 and C_4 . Prefecture C_5 is not lying on the frontier and it is considered either as less efficient or not efficient. Point C_{μ} on the surface, which determines the optimal level of efficiency, represents the combination of the two ratios R_1 and R_2 in the same proportion as prefecture C_5 and thus it is considered as the reference point, which is used for the measurement of relative efficiency of prefectures C_5 is prefectures C_2 and C_3 . The portion by which C_{μ} prevails C_5 shows us the size of inefficiency. The degree of efficiency for prefecture C_5 is found by the ratio of the distances OC_5/OC_{μ} .

Let us now consider the problem from the mathematical point of view. The N under consideration prefectures produce a vector of outputs R_i in the form of the mentioned financial ratios. The matrix of outputs R_i (with i=1,2,3,...,m) is known for each prefecture n (with n=1,2,...,N). The n+1 variables to be determined are a set of weights⁴ (λ), (λ = λ_1 , λ_2 , ..., λ_{κ})^{ℓ} placed on each of the prefectures in forming the efficiency frontier for prefecture (ℓ) and an efficiency measure Θ^{ℓ} .

Then the linear program for each prefecture can be written as:

$$\begin{array}{ll} \max & \mathcal{G}_{\ell} \\ \text{subject to} & \displaystyle\sum_{n=1}^{N} \lambda_n R_{in} \geq \mathcal{G}_{\ell} R_{i\ell} \quad (i = 1, 2,, m) \\ & \displaystyle\sum_{n=1}^{N} \lambda_n = 1 \\ & \mathcal{G}_{\ell} \geq 0 \\ & \lambda_n \geq 0 \quad (n = 1, 2,, N) \end{array}$$

The efficiency score for each prefecture is given by $\Theta_{\ell}^* = \frac{1}{\vartheta_{\ell}}$, and it is positive

and less than or equal to one. DMUs with Θ^* value of unity are deemed efficient while DMUs with a Θ^* score of less than one are considered as inefficient. The optimal weights

 $(\lambda_1^*, ..., \lambda_n^*)^{\ell}$ of the reference group in the solution set a feasible target for improvement in each ratio (R_i) for prefecture ℓ .

$$\hat{\mathbf{Y}}_{i\,\ell} = \sum_{n=1}^{N} \lambda_n^* R_i \quad \text{or} \quad \hat{\mathbf{Y}}_{i\,\ell} = R_{i\,\ell} \Theta_{\ell}^* + s_{i\,\ell}$$

where $(s_{i\ell})$ is the slack on ratio (i) and reflects the non-proportional residual output slack, while (Θ_{ℓ}^*) reflects the proportional output augmentation. In the number of cases where a DMU exhibited a negative ratio, the constraint associated with the negative ratio was amended to the following:

$$\sum_{n=1}^N \lambda_n R_{in} \geq R_{i\ell}$$

This ensures that the reference group exhibits performance not worse than a reference prefecture on the ratio on which this prefecture has negative performance along the lines suggested by Banker and Morey (1986) and Smith (1990).

The analysis of weights is particularly instructive when we consider prefectures, which seem to be efficient ($\Theta^*=1$). The weights indicate whether this efficiency is a result of exceptional performance in just one or two dimensions. A prefecture may choose to concentrate on just one output producing an exceptional performance along that dimension. Then whatever the performance along other outputs this prefecture will be deemed efficient. There is simply no other prefecture with which to compare it. This is a drawback of DEA and shows the difficulty of interpreting apparent efficiency in prefectures adopting unusual patterns of outputs (or inputs). The weights derived in this way show the importance given on the output by the prefecture under consideration. DEA makes no judgments about the validity of such values and limits the search for optimal performance amongst comparison groups adopting similar values.

5. EMPIRICAL RESULTS

According to the derived results from the solution of the model, it emerges that the annual efficiency ratios of the Greek prefectures range from 0.4256 to 1. Twelve prefectures are considered to be efficient for the year 2000, ten for the year 1990 and nine for the year 1980 in the case of CRS. Specifically, as can be seen from Table 4, efficient prefectures are considered to be those with efficiency ratio equal to one (Θ *=1). In all years the most efficient prefectures are c6, c14, c43 and c49 in the case of CRS and c6, c14, c18, c21, c43, c45 and c49 in the case of VRS⁵.

The first column in Table 4 represents the prefectures, the second, fifth and eighth columns the efficiency scores, the third, sixth and ninth columns the reference set for the inefficient prefectures compared to the efficient ones, whereas the fourth, seventh and tenth columns show the rank of prefectures according to their efficiency. The same column shows us how many times the efficient prefectures constitute a reference and comparison criterion for the inefficient prefectures (the numbers in parentheses). That is, how many times the specific prefecture appears to be a member of the reference set.

At this point it is worth mentioning that a prefecture which appears to be in the efficient frontier for the less efficient prefectures, the most times, is considered to be the Global leader. By counting the times each prefecture appears to be in the reference set (Table 4), we notice that prefecture C_6 is the most efficient in the case of CRS and for the years 1980 and 1990. That is, this prefecture appears 38 times (more than all the other efficient prefectures) to be part of the reference set in the year 1980 (CRS) and 40 times in the year 1990 (CRS). This means that its performance is greater on average in all dimensions of efficiencies as they are described in our model compared to the other efficient sample prefectures. Similarly, in the case of CRS C_{49} in 1990 (35) and in 2000 (16) and C_7 in 2000 (40) are the most efficient prefectures.

Table 4: Rankings and benchmarks per prefecture in the case of Overall efficiency

As it can be seen from the mathematical formulation, the feasible target for the improvement of every ratio is achieved by summing up the products of the weights (λ_i) and the respective ratios $(R_i)^6$. The ratios used for each prefecture's efficiency as well as the feasible target for improving any ratio are shown in Table 5. We notice that for the prefectures forming the efficient frontier, there is no difference between the real ratios and the feasible targets. On the other hand, there is a possibility of improvement for all prefectures whose efficiency, according to Table 4, is less than 1.

It is worth mentioning that Table 4 must be read along with Table 5, as both Tables refer to the case of CRS. For instance, let us examine prefecture 2 (C_2). By looking first at Table 4, we notice that the reference set of C_2 is C_6 , C_7 , C_{45} and C_{49} . This means that C_6 defines by 0.1793, C_7 by 0.044, C_{45} by 0.0998 and C_{49} by 0.6833 feasible improvement targets of all C_2 's ratios. So, as it is shown in Table 5, the feasible target for the respective C_2 's ratios will be given as the sum of the products of the respective weights for the reference set (C_6 , C_7 , C_{45} and C_{49}) of C_2 multiplied by the matrix-columns that include the ratios of the reference set prefectures. Specifically, the feasible target for every inefficient prefecture (say C_2) can be calculated as:

$$\hat{\mathbf{Y}}_{i\,2} = \sum_{n=1}^{N} \lambda_n^* R_i$$

Table 6 presents the scale efficiency of all the Greek prefectures. These are computed by dividing the efficiency results derived in the case of CRS by the results derived in the case of VRS. If scale inefficiency exists this may be due to either increasing (IRS) or decreasing returns to scale (DRS). We differentiate IRS from DRS by solving the same Linear programming problem imposing the restriction that the sum of weights is less or equal to 1 allowing for non-increasing returns to scale (NIRS). That is $\sum_{r}^{N} \lambda_{sr} \leq 1$. If the efficiencies derived from the case of VRS equals to the efficiencies derived for the NIRS then we have scale inefficiency due to DRS. If they are not equal then the scale inefficiency is due to IRS.

Table 6: Scale Efficiencies and returns to scale

For comparing the results derived in our analysis we form three different groups of prefectures according to their efficiency scores. In this way, group 1 is formed by those prefectures that are efficient ($\Theta^{*}=1$), group 2 includes prefectures with scores less than 1 and more than 0.7 ($0.7 \le \Theta^{*} \le 1$) and the last group includes prefectures with scores less than

0.7. All the groups along with the prefectures are presented in Table 7. The rank of prefectures in table 7 is according to their efficiency scores in each year. As it appears, in the last three decades we have an increase of efficient prefectures (group 1), where over the same period we have a decrease for the prefectures of group 2. At the same time, the number of the most inefficient prefectures is stable for the last three decades (group 3).

Table 7: Groups of prefectures according to their efficiency scores

Let us now compare the groups between them (groups 3 with 2, 2 with 1 and 3 with 1) in order to establish the main factors/ variables affecting their efficiency. In doing so, we observe that there is a decrease in the number of hospitals (NHO) as well as in the number of doctors (NDO) for the first decade. Then for the other two decades there is a slice increase. In the case of the number of public schools (NPUS), there is a decrease in the first two decades and an increase in the last one. Over the three decades the number of busses (NPUS) among the Greek prefectures is fluctuating, with a minor decrease for the first decade and then an increase. Comparing GDP among the three groups over the decades we

observe that there is a substantial increase between the groups and over the decades. The same behaviour has been also observed in the case of new houses (NNH). However, in the case of DUR the less efficient prefectures have an increase of rural population whereas the efficient prefectures have more balanced population with a trend of an increase in urban population over the decades.

Table 8 presents the percentage changes in inputs and outputs for the year 2000 for each of the inefficient prefectures in order for them to become efficient. Let us clarify that by cutting services in certain areas to increase efficiency means that we use inputs more efficiently as there are interactions between them as well as second round effects. These multiple input ratios are used in order to maximize the output levels of prefectures.

As can be seen, the inefficient prefectures (the majority) need to use efficiently the number of hospital beds in order to become efficient. For instance the prefecture of Messinia (C34, MES⁷) need to decrease the number of hospital beds (NHO) by 48.5%, whereas the prefecture of Keffalonia (C24, KEF) needs to decrease them by 49.6% and the prefecture of Arkadia (C3, ARK) by 62.8%. The biggest increase in hospital beds by 32.3% is observed in the prefecture of Prebeza (C39, PRE) in order to become efficient.

Looking at the number of doctors (NDO) we realise that for most of the prefectures their current levels require a reduction in order to become efficient. The prefecture of Kerkira (C23, KER) needs to decrease the current number of doctors by 41.4% and the prefectures of Imathia (C15, HMA) and Lasithiou (C30, LAS) by 51.7% and 56.3% respectively. Similarly, an increase in doctors by 0.68% and 91.5% needed to be taken for the prefectures of Fokida (C48, FOK) and Prebezas (C39, PRE) respectively

Moving on to the public school provision (NPUS) policies must have the effect of a small decrease in the number of schools provided for the majority of the prefectures. The limited number of students enrolled in these schools explains this probably. More

specifically, the prefectures of Trikala (C44, TRI) and Evia (C11, EVI) need to decrease the current number of public schools provided by 9.3% and 17.8% respectively. The major decrease is observed in the prefecture of Rodopis (C41, ROD) with a

L	.,.=•	·	, 2	.,	.,	-,			. ,

Table 8: Percentage change (per indicator/variable) for achieving efficiency (year 2000)

percentage decrease of 47.8%. On the other hand, there is a need for increase in public schools provided in some prefectures like Thesproteias (C17, THP), Prevezas (C39, PRE) and Attikis (C37, ATT) by 8%, 7.4% and 5.4% respectively.

In the case of public busses (NPB) reductions in their number is recommended for the inefficient prefectures in order to become efficient. For instance, the prefectures of Kerkira (C23, KER), Attiki (C37, ATT) and Thesproteias (C17, THP) the decrease is coming up to 35%, 39.94% and 60.48% respectively. Exceptions are Fokida (C48, FOK), Pierias (C38, PIE) and Prebeza (C39, PRE) where an increase in the provision of public busses by 0.62%, 0.19% and 86.9% is recommended.

Furthermore, in the case of GDP for all the inefficient prefectures an increase in their current levels is required in order to become efficient. The smallest increase of 0.85%, 2.89%, and 2.92% is suggested for Korinthia (C26, KOR), Messinias (C34, MES) and Evias (C11, EVI) respectively. Similarly, the greatest increase of 114.1%, 132.6% and 926.14% is noticed in Irakleiou (C16, HRA), Ioanninon (C19, IOA) and Kilkis (C25, KIL) respectively.

Moreover, observing the difference between urban and rural population, we notice that there is a tendency towards an increased gap due to the increase in the rural population. An increase in the difference of urban and rural population is suggested for the prefectures of Ioanninon (C19, IOA), Dramas (C8, DRA) and Kastorias (C22, KAS) by 132.6%, 110% and 105% respectively. But, the largest decreases are required for the prefectures of Xiou (C51, HIO), Imathias (C15, HMA) and Xanion (C50, HAN), by 451%, 175.1% and 342.2% respectively.

Lastly, for the inefficient prefectures it is suggested that they must enhance their policies of creation of new houses in all cases. The greatest increase is suggested for the

prefectures of Ioanninon (C19, IOA), Irakleiou (C16, HRA) and Prebezas (C39, PRE) by 132.6%, 114.4% and 158.3% respectively. The smallest increase is suggested for the prefectures of Keffalonias (C24, KEF), Evias (C11, EVI) and Messinias (C34, MES) by 3.4%, 2.9% and 2.8% respectively.

6. Conclusions and Policy Implications

In this study, performing an application of DEA to the Greek prefectures, we obtained, among others, the efficiency scores and the optimal ratios levels for inefficient prefectures for the last three decades. In the case of the Greek prefectures the quality of life is strongly associated with the regional development of the particular prefectures. The efficient prefectures seem to have definite and strong characteristics. According to our empirical analysis

- It is clearly defined that two are the factors, which characterize and distinguish the efficient prefectures from the inefficient ones. Namely, the efficient use of resources (in our case NHO, NDO, NPB, NNH) and the high rates of GDP.
- The quantity of the resources of a prefecture doesn't necessarily ensure the efficiency of this prefecture. On the contrary and in order for a prefecture to attract a certain quantity of resources it has to develop the appropriate mechanisms to make efficient use of them. Obviously, the role of governments and policy makers is substantial in stimulating the proper use of the resources provided by these mechanisms. Moreover, if these mechanisms don't exist, they must be created before the recourses are allocated.
- The policy makers must observe living standards and regional development as a solid parameter, which eventually has a direct effect on the economy.

• When policies are taken regarding a prefecture's development both the parameters of competition and collaboration with capital spillovers must be taken into account before any development policy is being applied.

Over the last three decades, millions of \in have been spend from the Greek governments in order to enhance the economically underdeveloped prefectures. However, capital spillovers have been observed through internal trade between the efficient prefectures and the inefficient ones. At the same time, internal competition among the Greek prefectures, in order to attract as many funds from the Greek governments as possible, has been created. More specifically, in Fig. 1(b, c, d) the development of the Greek prefectures through the three decades is graphically presented.

Clearly we can define the efficient prefectures over the three decades. In the case of Attiki (C37, ATT), we observe that it has been efficient and developed over the three decades. But spillovers through trade have been also observed in the case of Boiotias (C6, BOI), which is geographically located next to the capital of Greece. The cooperation between the two prefectures over the decades has been the reason of efficiency in the case of the prefecture of Boiotias. However, this cooperation has created a competition with the other prefectures around the capital of Greece (Attiki). For instance, the prefectures of Evias (C11, EVI), Korinthias (C26, KOR), Argolidas, (C2, ARG), Fdiotidas (C46, FTH) and Fokidas (C48, FOK), have been inefficient over the three decades even though they are near (geographically) to the Greek capital. Similarly, in Northern Greece, the prefectures of Halkidikis (C49, HAL), and Serron (C43, SER) have been efficient over the decades whereas, their neighbors' prefectures of Dramas (C8, DRA), Kavalas (C20, KAV), Kilkis (C25, KIL), Pellas (C36, PEL), Imathias (C15, HMA) and Pierias (C38, PIE) have been inefficient and underdeveloped over the three decades.

Resource allocation through different policies has been the cause of underdevelopment of the Greek islands, although in the last decade an attempt from policy makers to distribute the resources (funds, capital mainly from EU) to the islands and to inefficient prefectures over the years can be seen. That is the case for the islands of Kikladon (C27,KYK), Xiou (C51, HIO), Lesvou (C31, LES) and the prefecture of Evrou in the mainland (C10, EVR).

All the above findings imply that the Greek policy makers must find those policies that stimulate better and more efficient resource allocation for more effective public provision services. However our intension was to use DEA as a benchmarking tool in identifying the efficient Greek prefectures in terms of living standards and regional development, but in all cases the results should be viewed as indicative rather than definitive of the Greek State's regional and social development policy. The results would thus be strengthened by a more thorough investigation taking into account more factors affecting the social and economic environment of Greece.

ENDNOTES

1. It is usually assumed that the relationship between the variables is linear.

2. The indicators used are pollution density, non-agricultural population as percentage of total population, urban planned area as a percentage of total area, commercial area as a percentage of total area, average current household income, local government expenditure per capita, number of local telephone subscribers per 100 people, piped water supply of population served, number of physicians per 10000 residents, copies of newspaper and magazines sold per 1000 people and the percentage of population over the age of 15 with education of high school or higher.

3. Relying on the exciting literature we have used these ratios as far as they are representative of Health, Education, Living Standards, Economic and Regional Development. Due to high correlation coefficients among the 19 initial selected variables we ended up to the final four input and three output ratios used. The excluded ratios from our analysis were: number of cars, hotel beds, telephone lines, dentists, drugstores, space m³ of new houses, usage of electricity (all per 1000 citizens), number of academic staff per 1000 students, numbers of primary, high school and lyceum students (all per teacher), percentage of employment and births per citizen.

4. If a prefecture wishes to improve its score it would be best to concentrate on those outputs with the highest weight, as the efficiency score is most sensitive to those outputs.

5. Results on VRS are not presented here but are available to the readers on request.

6. For simplicity, these weights are not presented but are available to the readers on request.

7. These are the prefecture and map codes (see table 1)
