# **Real Effective Exchange Rate and Manufacturing Sector Performance: Evidence from Indian firms**

---

## **Abstract**

We explore the impact of Real Exchange Rate changes on the performance of Indian manufacturing firms over the period 2000-2012. Our empirical analysis shows that real exchange rate movements have a significant impact on Indian firms' performance through the cost as well as the revenue channel. The impact depends upon the share of imports & exports along with the degree of market power as reflected in the time varying firm level mark up. However, presence of overvaluation negates the beneficial effects of exchange rate appreciation operating through the lower input cost channel. The same cannot be said about the 'price competitiveness' effect working through the export channel.

**Keywords:** *Real Exchange Rate, Manufacturing Performance, Mark up*

## I. Introduction

International economics has long been concerned with the effects of exchange rate movements on the real economy. The topic continues to attract theoretical as well as empirical researchers alike. This paper contributes to the large body of empirical literature looking at the impact real exchange rate on firm level performance by using a newly compiled dataset of around 300 Indian manufacturing firms. We find several interesting results with regards to the importance of real exchange rate movements in influencing the performance of Indian manufacturing firms. The results and their implications are discussed in detail below.

India presents a unique case for studying the impact of exchange rate movements. Prior to the Balance of Payments crisis in 1991, Indian Rupee was pegged to a basket of currencies dominated by the US Dollar. The external payment crisis of 1991 forced the Reserve Bank of India (RBI) to implement a set of market oriented financial sector reforms and a paradigm shift from fixed to market-based exchange rate regime in March 1993.<sup>1</sup> Institution of Current Account convertibility in August 1994 and gradual liberalization of Capital Account along with other trade and financial liberalization measures meant a rise in total turnover in the foreign exchange market by more than 150% from USD 73.2 billion in 1996 to USD 130 billion in 2002-03 and further to USD 1100 billion in 2011-12<sup>2</sup>. A direct outcome of these changes has been a rise in the volatility of Indian Rupee. Figure 1 plots annual volatility of monthly Rupee-USD log returns to illustrate this point.

Figure 1

In this backdrop, RBI exchange rate management policy has aimed at maintaining orderly conditions in the foreign exchange market by eliminating lumpy demand and supply and preventing speculative attacks, without setting a specific exchange rate target. RBI has used a combination of tools including sales and purchase of currency in both the spot and the forward segments of the foreign exchange market, adjustment of domestic liquidity through the use of Bank Rate, CRR, Repo rate etc. and monetary sterilization through specialized instruments<sup>3</sup>. An

<sup>1</sup> See the Special edition of RBI's *Reports on Currency and Finance*, Vol. III (2005-06) for detailed discussion on the evolution of India's foreign exchange market. (Link: <http://rbidocs.rbi.org.in/rdocs/content/PDFs/89704.pdf>) See Sengupta and Sengupta (2012) for a discussion on India's Capital Account Management between 1990-2011.

<sup>2</sup> Table A in Appendix presents the growth in the size of foreign exchange market in India over time.

<sup>3</sup> For instance, RBI resorted to a net purchase of 5.4 billion USD between April-August 1997 to reduce the acute upward pressure on Rupee resulting from buoyant capital inflows and sluggish import demand. Then, as Rupee weakened in the last week of August, partly in response to the East Asian financial crisis, RBI sold foreign exchange worth 978 million USD to strengthen the Rupee. Again, a surge in capital inflows

interesting feature of RBI's intervention during this period has been asymmetry during episodes of appreciation and depreciation.

Figure 2

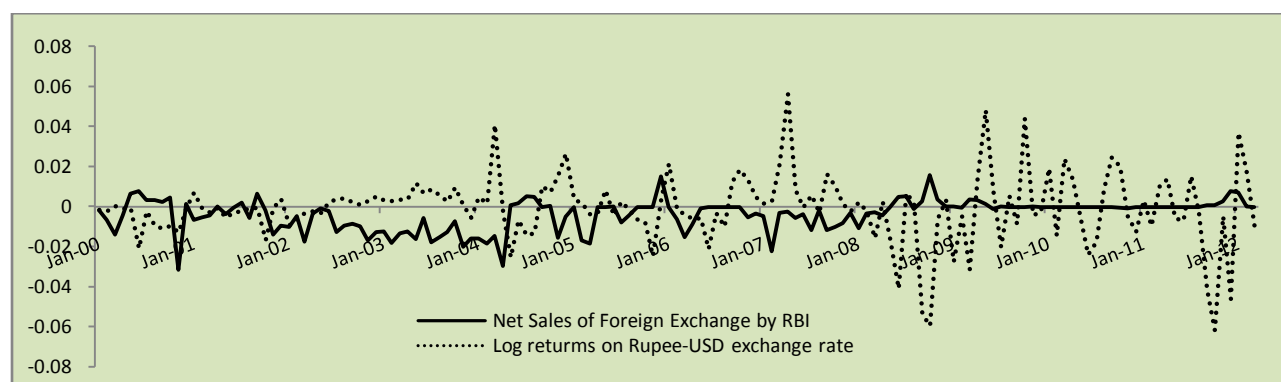

Figure 2 plots Net Sales of Foreign Exchange Assets by RBI as a percentage of total turn-over in the foreign exchange market<sup>4</sup> along with monthly log returns on Rupee – USD exchange rate<sup>5</sup>. One can see that RBI has been intervening actively in the foreign exchange market during episodes of Rupee appreciation by purchasing foreign exchange while following a hands-off approach during episodes of Rupee depreciation. Underlying this asymmetry has been the notion that an appreciated Rupee would hurt exporters through a loss in cost competitiveness and by corollary, adversely affect India's growth performance. Empirical evidence on the impact of exchange rate on the performance of Indian firms is however non-existent<sup>6</sup>. Present paper tries to fill this important gap in the literature.

Exchange rate movements could affect firm performance through a number of channels, such as the cost of imported inputs relative to other factors of production, price of exports relative to foreign competitors or the cost of external borrowing. Although the impact on firm performance is only one component determining how exchange rate changes affect aggregate economic growth, it can be an important and significant determinant of the same. Our paper looks at the short term and long term effect of real exchange rate change on firm performance using data on roughly 300 Indian firms. An important advantage of using firm level panel data is that it allows us to control for unobservable firm level effects. Although unmeasured, these individual idiosyncrasies reflect important characteristics of a firm, which are likely to influence its response to exchange rate movements. We use time varying firm specific mark-ups along with firm and industry specific dummies to capture heterogeneity in firm's response to exchange rate changes.

Main findings of the paper are that real exchange rate changes affect long term and short term firm level performance through cost as well as revenue channels but the impact is more pronounced for firms with smaller market power. The results hold true for various alternative measures of firm performance such as output growth, sales growth, income growth and growth in

---

starting 2004 forced RBI to purchase foreign exchange in order to ward off the upward pressure on Rupee. This time around RBI's intervention was sterilized using *Market Stabilization Scheme* bonds issued specifically for this purpose.

<sup>4</sup> Negative net sales implies net purchase of foreign exchange by RBI

<sup>5</sup> Positive return implies appreciation of Rupee.

<sup>6</sup> Recent paper by Rajeshwari Sengupta (2012) being the only exception.

market capitalization. Real exchange rate appreciation benefits firms with higher dependence on imported inputs through a lower variable cost while it hurts the firms with a greater dependence on exports through lower `price` competitiveness. The effect is more pronounced for firms with lower market power. Another interesting finding of our paper is that overvaluation in exchange rate negates the beneficial effect of exchange rate appreciation through the `cost` channel even though it does not significantly affect the impact through the revenue channel. This highlights another channel through which an overvalued exchange rate can adversely affect a country's growth performance.

The paper is organized as follows – Section 2 provides a brief review of the literature. Section 3 describes the dataset in detail. Section 4 lays the empirical methodology and presents our results. Section 5 concludes.

## **II. Literature Review**

Our paper is related to a large body of microeconomic literature looking at the impact of exchange rate fluctuations on firm level performance. A section of this literature looks at the impact of exchange rate changes on firm's value measured by its stock returns. Examples of this literature include Adler and Dumas (1984), Jorion (1990), Bodnar and Wong (2000), Dominguez and Tesar (2006), Parsley and Popper (2006).

Another strand of the same literature looks at the issue of pricing policies in response to currency fluctuations (for e.g. Goldeberg and Knetter (1997)). Finally a small section of this literature looks at the impact of currency fluctuations on firm level variables such as investment or employment (e.g. Goldberg (1993), Campa and Goldberg (1995, 1999), Nucci and Pozzollo (2001), Demir (2010)). While this paper is most closely related to the last strand of literature, most of the existing papers in this literature look at developed countries with little attention being paid to the emerging markets such as India. One of the reasons for this gap is the lack of good quality firm level data. In that respect our paper contributes to the existing literature by putting together a large firm level dataset for an emerging economy that can be used to answer questions regarding impact of macroeconomic variables such as exchange rates on firms.

Finally our paper is also linked to the literature on cost of sharp currency devaluations. While theory has been ambivalent regarding the impact of currency devaluations on real activity, empirical literature has also provided mixed evidence regarding the economic impact of sharp currency devaluations (see for example Hutchison and Noy (2005), Hong and Tornell (2005) and Gupta et al (2007)). Unlike most papers in this literature however, we use firm-level longitudinal data set for an emerging market that allows us to take in to account firm level characteristics including firm level export and import shares and firm level mark ups.

## **III. Data**

Our primary source of data is the PROWESS database compiled by the Centre for Monitoring Indian Economy. The original database contains financial performance of over 27,000

companies. Out of these we include 250 manufacturing firms listed on the Bombay Stock Exchange (BSE) and included in the BSE 500 index over the period 2000-2012. Firms included under the BSE 500 index represent roughly 93 percent of the total market capitalization on the BSE and cover all the major industries in the Indian economy including construction, infrastructure, as well as non-traditional services such as software and ITeS. Since our focus is on manufacturing firms, we only include those in our sample. We also check our sample for potential outliers. One firm for which data appeared obviously misreported was removed from the sample.

To check how well our sample captures fluctuations in aggregate data we plot change in output growth and investment in the sample and aggregate data in the figures below. Our sample manages to capture broad trends in aggregate data reasonably well. After rising steadily between 2004 and 2007, output growth and investment declined in the aftermath of the 2008 crisis. While the output growth recovered quickly before slowing down for a second time 2010, investment maintained a sustained downward trend after 2008.

Figure 1

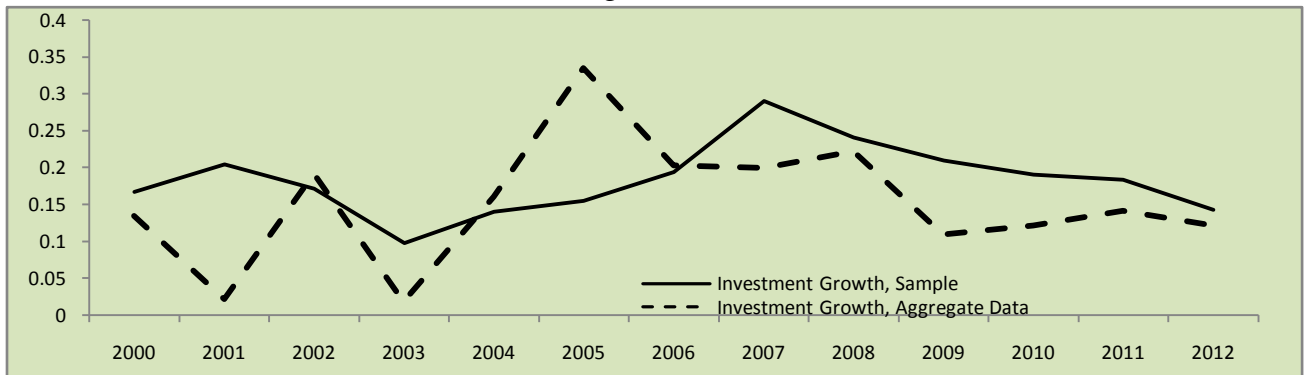

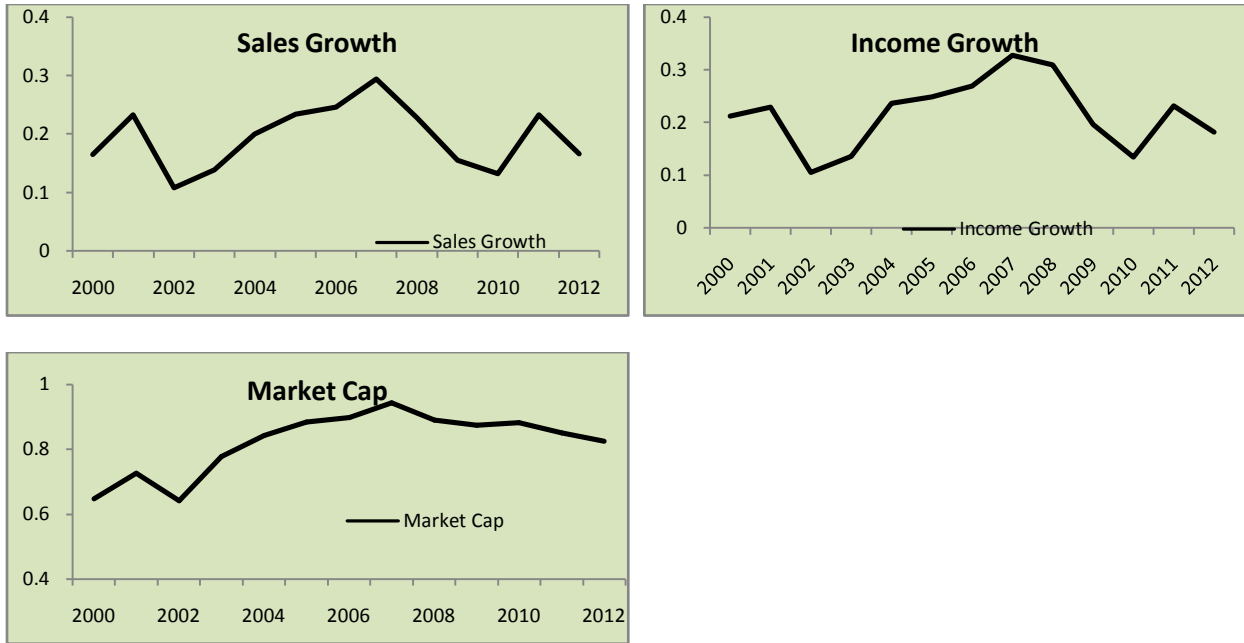

Figure 2

Plots of average sales growth, income growth and market capitalization present a similar picture. There is an increase in sales, income and market capitalization between 2004 and 2007 followed by a downturn in 2008 due to global financial crisis that originated in the US.

Figure 3

Text table 1 provides industry wise composition of our sample along with key characteristics such as output growth and trade shares. The first column gives the total number of observations for each sector in the entire sample followed by the share of each industry in total output in the second column. Metal and metal products constitute the largest percentage in terms of the number of observations followed by Chemicals and Food. Refinery constitutes the single largest sector in terms of its share of output followed by Metal products and Food.

The last two columns give industry wise average share of exports in total sales and share of imports in total intermediate inputs in year 2012 – both, indicating the trade orientation of each sector. In terms of trade orientation, Refinery has the largest share of exports in total sales as well as the largest share of imports in intermediate inputs. Transport equipment has the smallest degree of trade orientation as measured by the sum of export and import shares. As discussed above, shares of exports and imports have an important bearing on the impact of exchange rate movement on firm’s performance. Data appendix gives year wise export and import shares for each of these industries. A larger share of exports in total revenue implies that an increase in price competitiveness following currency depreciation is likely to boost revenues, income as well as expected future profits of the firm. Similarly, the larger is the share of imported inputs in total cost, the greater is the increase in cost of production and the decline in current and future profits after exchange rate depreciation. The empirical model that follows incorporates firm specific export and import shares.

**Text Table 1**

Industry	No. of Obs.	Share in Output (%)	Average Export Share	Average Import Share
Metal & Metal Products	496	8.7	0.19	0.32
Chemicals	342	1.7	0.098	0.34
Machinery	243	2.7	0.10	0.18
Electronics	54	0.65	0.06	0.13
Textiles	179	1.1	0.22	0.22

Wood & Leather	72	0.16	0.06	0.15
Refinery	126	41.6	0.33	0.74

#### IV. Empirical Methodology

Our baseline specification includes the standard output growth equation augmented with real exchange rate change interacted with time varying import and export shares of each firm. Equation 1 presents our base line specification:

$$\Delta y_{t,i} = \beta_1 \Delta l_{t,i} + \beta_2 \Delta k_{t,i} + \beta_3 \Delta ulc_{t,i} + \beta_5 \alpha_{t-1,i} \Delta e_t + \beta_6 \eta_{t-1,i} \Delta e_t + b' Z_{t,i} + \tau_t + v_{t,i} \quad (1)$$

$\Delta y_{t,i}$  is the growth rate of output of firm  $i$  defined as the difference in log of output.  $\Delta l_{t,i}$  is the growth rate of labor while  $\Delta k_{t,i}$  is the growth rate of capital i.e. investment<sup>7</sup>.  $\Delta ulc$  is the growth rate of unit labor cost used as a proxy for productivity growth<sup>8</sup>. The first three variables on the right hand side can be derived easily from the basic Cobb-Douglas production function.

To this basic specification we add two terms capturing the impact of real exchange rate movements. The first term  $\alpha_{t-1,i} \Delta e_t$  is the product of log difference in 36 country trade weighted real effective exchange rate index (REER from now on) of Rupee,  $\Delta e_t$ <sup>9</sup> and  $\alpha_{t-1,i}$  - lagged share of imports in intermediate inputs. Firms with a higher share of imported inputs are likely to benefit more from Rupee appreciation on account of reduced variable cost. One therefore expects the coefficient on this term to be positive. Using similar logic, one would expect the coefficient on  $\eta_{t-1,i} \Delta e_t$  - product of lagged export share and real exchange rate change - to be negative. Use of lagged import and export shares is done deliberately in order to avoid endogeneity bias induced by the possible correlation of these shares with the exchange rate.  $Z_{t,i}$  is a set of industry specific and size dummies. In addition, we use year dummies  $\tau_t$  to account for year specific effects. We use random effects estimator to estimate our model as suggested by Hausmann's

<sup>7</sup> Growth rate of labor is calculated as the change in log of total number of workers employed while investment is calculated as the log difference in Gross Fixed Assets (this includes land and plant and equipment for production)

<sup>8</sup> Unit labor cost is calculated as the ratio of total worker emoluments and output.

<sup>9</sup> REER index is defined so that an increase denotes appreciation of Rupee.

specification test. To check the robustness of our results we replace output growth with income and sales growth.

Table 1 below presents the results of this exercise. Starting with the key variables, we find labor and investment growth to be positively correlated with output, sales and income growth and unit labor cost growth to negatively correlated with the same. All the coefficients are significant at 1 percent and have theoretically correct sign. Next we look at the coefficients on the two exchange rate terms. Once again, coefficients on both the terms have theoretically expected signs but the coefficient on real exchange rate interacted with the share of imports appears statistically insignificant. Overall, it appears that the `price competitiveness` effect of exchange rate appreciation operating through the revenue channel is stronger than the `cost` effect operating through lower price of imported inputs. This result is in contrast with studies like Nucci & Pozzolo (2001) that find a significant impact of both import and export channels on firm level investment. An important determinant of firm's response to exchange rate movements is their market power. Firms with a lower degree of market power are more likely to experience greater impact of exchange rate movement as compared to the firms with a higher degree of market power. We explore this relationship in the next section.

### Market Power

Dornbusch (1987) Nucci (2001), Goldberg (1999) show that impact of exchange rate movement on firm's investment growth is inversely related to the degree of their market power. Following their insight we include a measure of market power in our extended model. Following Domowitz, Hubbard and Petersen (1986) we define firm's markup as –

$$AMKP = \frac{\text{sales} + \text{change in inventories}}{\text{payroll} + \text{cost of materials}} \quad (2)$$

In the absence of data on marginal cost of production, the measure given in equation (2) is commonly used in empirical literature. PROWESS data set provides information on sales, inventories, worker's compensation and intermediate inputs for each firm; allowing us to calculate time varying firm specific mark ups. Text Table 2 presents industry wise average mark ups.

Text Table 2

Industry	Average Mark up
Metal & Metal Products	4.15
Chemicals	5.5
Machinery	2.5
Electronics	3.3
Textiles	6.1
Transport Equipment	1.9
Plastic & Rubber	1.8
Food	4.4
Wood & Leather	2.7
Refinery	4.4

In order to capture the effect of market power on the relationship between firm's performance and exchange rate changes, we multiply the reciprocal of lagged mark up,  $mkp_{i,t-1}^{-1}$ , with the two exchange rate terms ( $\alpha_{i,t-1} \times \Delta e_t$  &  $\eta_{i,t-1} \times \Delta e_t$ ) in our baseline specification. Table 2 presents the results from this exercise. Introduction of mark ups makes coefficients on both the exchange rate terms significant with theoretically expected signs. The estimated coefficient of the interacting variables  $\alpha_{i,t-1}, \Delta e_t$  and  $mkp_{i,t-1}^{-1}$  is positive, suggesting that for a given share of imported inputs in total costs and a constant path of currency depreciation, lower price-cost margins are associated with a larger reduction in output, income and sales. Opposite is of course true in case of a currency appreciation. On the revenue side the coefficient on  $\eta_{i,t-1} \times \Delta e_t \times mkp_{i,t-1}^{-1}$  is negative indicating that the effect of exchange rate depreciation on output and income is positive and increases with the exposure to export markets; on the contrary, it decreases with the market power of the firm, as measured by  $mkp_{i,t-1}^{-1}$ . Coefficients on other variables remain same as before.

Overall the results so far confirm the predictions of economic theory. However, we have assumed that exchange rate elasticity is homogenous across sectors. It is likely that the impact of exchange rate movements varies across sectors depending upon differences in the degree of import penetration in the domestic market, substitutability of imported inputs etc. Given the sample size, it is not possible at this stage for us to estimate separate regressions for each sector. In its place we try to incorporate industry dummies in our model to capture parameter heterogeneity. Next section provides the details of this exercise.

### **Parameter heterogeneity**

As discussed in the last section, elasticity of exchange rate is likely to vary across sectors depending upon factors such as import penetration, input substitutability etc. We there for multiply the exchange rate terms with industry dummies and incorporate these interaction terms in our model Table 3 presents the results from this exercise.

The results in Table 3 show that this specificity introduces a degree of heterogeneity (at the industry level) in the effect of exchange rate variations on income and output, which is statistically significant. The Wald test for the hypothesis that these sectorial effects are identical is in fact rejected (14.6; p-value 0.06 for import share and 123.8, p-val 0.00 for export share). Moreover, the coefficients of the other terms in the model are still significant and of the correct sign, showing the robustness of our earlier results.

### **Exchange Rate and Overvaluation**

One aspect of firm performance in the face of exchange rate is the degree of exchange rate misalignment. If exchange rate is overvalued to begin with then currency appreciation is likely to affect firm performance adversely while depreciation is likely to prove beneficial. We test this implication by incorporating a measure of exchange rate overvaluation in our baseline model.

Exchange rate overvaluation is defined as deviation from the Hodrik-Prescott filtered trend. We define overvaluation dummy that takes a value of one whenever the actual REER is above trend. To incorporate overvaluation in our model we multiply exchange rate terms with the overvaluation dummy and include them in our model. Table 4 presents the results from this exercise. As we can see, the two overvaluation terms are negative though only first term with import share is significant while the remaining variables maintain their original signs and significance. These results can be interpreted as follows – exchange rate depreciation (appreciation) affects firm's performance through `cost` as well as `revenue` channels and these effects vary with the degree of international trade integration as measured by export and import shares and the degree of market power measured by the inverse of mark up. The impact also varies depending upon whether the exchange rate is overvalued. In particular, the positive impact of an exchange rate appreciation through lower input cost is almost fully reversed when the exchange rate is overvalued. In other words, firms with significant dependence on imported inputs benefit from an exchange rate appreciation but only when exchange rate is not overvalued. On the revenue side, exchange rate depreciation benefits exporters but the benefit does not show a significant change in case of an overvaluation (the sign is negative, however, indicating a greater gain in `cost` competitiveness under overvalued exchange rate).

### **Market Capitalization**

In the last part of our empirical analysis we look at long-term effect of exchange rate movements on firms. We use change in market capitalization as a percentage of firm's value to capture actual and expected long-term growth performance of firms. Table 5 presents the results from this exercise. Once again, exchange rate change affects firm's market capitalization through cost as well as revenue channels. The effect varies with the share of imports, exports and firm's markup. Overvaluation of exchange rate does not change the effect of exchange rate on market capitalization growth. While we do not find a significant coefficient on other variables like labor, capital and productivity growth, the industry, year and size dummies are jointly significant indicating presence of time and industry specific effects.

### **Conclusion**

This paper aims at laying out stylized facts regarding the impact of Real Exchange Rate change on firm's performance in the short run and the long run. We find a significant effect of real exchange rate movement on firm's performance through the cost as well as the revenue channel. The impact depends upon the share of imports & exports along with the degree of market power as reflected in the time varying firm level mark up. However, presence of overvaluation negates the beneficial effects of exchange rate appreciation operating through the lower input cost channel. The same cannot be said about the 'price competitiveness' effect working through the export channel. In addition, unobserved industry specific factors such as the degree of import penetration, degree of substitutability between domestic and imported inputs etc. also affect the extent to which exchange rate change affects firm's performance.

While the overall impact of exchange rate depends on the relative strengths of cost and revenue channels, our results provides important insights regarding the factors determining the impact of real exchange rate on firm level performance. For policy makers trying to assess the impact of exchange rate movements on real economy these results provide vital lessons. One drawback of the current study is that it only focuses on publicly listed firms which are likely to be larger in size and have better access to finance. It is possible that non-listed firms, which are smaller in size and have poorer access to outside finance, are affected more severely by exchange rate changes. It is equally possible that smaller firms respond to greater competitive pressure by lowering their mark up while bigger firms with greater market power reduce their volume of sales while maintaining their profit margins. These questions provide fruitful areas of future research.
