Finance and growth: New evidence from Meta-analysis

Simplice A. Asongu[1]

September 2013

Abstract
Purpose – In a meta-study, we have bridged the gap between the pros and cons of a questionable finance-growth nexus.

Design/methodology/approach – Over 20 fundamental characteristics that have influenced the debate over the last decades have been examined. The empirical evidence is based on 196 outcomes from 20 studies. We assess the degree of heterogeneity and identify causes of the observed differentiation.

Findings – Our findings also show evidence of publication bias. Overall, a genuine effect exists between financial development and economic growth. A finance-growth nexus might not be appealing in our era because of: endogeneity-based estimations, publication bias and, effects of financial activity. A historical justification has also been discussed.

Practical implications – Encouraging the publication of results with findings that are not consistent with the mainstream positive finance-growth nexus should provide new scholarly insights into the relationship. Depending on the specific context of sampled countries, the role of policy has also been to encourage financial development through measures that may expose countries to negative external shocks like financial crises. Policy makers that have been viewing the challenges of development exclusively from this point of view for the rewards of growth may not be getting the financial dynamics correctly.

Originality/value – Very few meta-analysis studies have focused on the finance-growth nexus.

Keywords: Meta analysis; Finance; Economic growth; Publication bias
JEL codes: C1; C4; E0; O0

1. Introduction

As far as we have reviewed, one of the themes that have ignited great interest with intense

debate and controversy among economic scholars and policy makers over the last decades is the

---

[1] Simplice A. Asongu is Lead economist in the Research Department of the AGDI (asongus@afridev.org).

finance-growth nexus. There is yet no definite consensus in theoretical and empirical literature on the relationship between financial development and economic growth[2]. While the first strand strongly advocates the high rewards of financial development on growth, the recent financial crisis has resurfaced the ghost of the second strand that is skeptical about the positive nexus.

Consistent with the first strand, financial services are important for economic growth as long as they improve productivity by promoting technological innovation and helping entrepreneurs with the best chances of success in the innovation process. It is argued that financial development would facilitate the mobilization of productive savings, efficient resource allocation, reduce problems of information asymmetry and improve risk management. It is further stressed that these effects could create a favorable macroeconomic framework for strong economic growth. This thesis has been strongly supported by a strand of endogenous growth models (Schumpeter, 1911; King & Levine, 1993; Beck et al., 2000; Nguena, 2012a,b).

Against the backdrop of the recent financial crisis and global economic meltdown, it has become abundantly clear that financial development could greatly penalizes economic growth in periods of financial crisis[3]. An abundant literature has been consistent with the view that the determining threshold remains the trade-off between financial instability and financial development in economic growth (Kaminsky & Reinhart, 1999; Demirguc-Kunt & Detragiache, 1998). While this skepticism is limited to the short-run (Loayza & Rancière, 2004; Eggoh, 2008), the higher appeals of finance in growth may not have been sufficiently sustained by the literature (Andersen & Tarp, 2003). With a substantial backing of empirical literature (Gregorio & Guidotti, 1992; Ram, 1999; Luitel & Khan, 1999), Andersen & Tarp (2003) have strongly

---

[2] Lucas (1988) even rejects the role of finance on growth as 'over-stressed'.
[3] It should also be noted that the global financial crisis shows what happens when regulations are poor or what happens when politicians meddle with the economy.

emphasized that the positive association between finance and growth becomes negative when the sample is limited to Latin American and African countries[4].

This pattern has set the course for a recent short-run Schumpeterian trip to embryonic African monetary zones to assess the thesis for positive spillovers of financial services on growth (Asongu, 2013a). A journey that has ended with mixed feelings because, while the trip has been promising for the East African Monetary Zone (EAMZ), it has been lamentable for the West African Monetary Zones (WAMZ). Results of the EAMZ (that are consistent with the traditional monetary policy arrangements) support the positive thesis whereas, those of the WAMZ (in line with the non-traditional strand of regimes in which policy instruments in the short-run cannot be used of offset adverse shocks to output) are sympathetic with the Andersen & Tarp hypothesis.

With the above interesting background, to the best of our knowledge, there are currently very few meta-studies that have addressed the underlying factors behind these conflicting results (Bumann et al., 2012; Senia, 2012). A meta-study could tackle the heterogeneity of the finance-growth nexus by providing the much needed synthesis that will throw more light into the debate. In this study, we rigorously combine outcomes from several papers in order to take the debate to another platform. By attempting to bridge the gap between authors advocating a positive nexus and sympathizers of Andersen & Tarp (2003), this paper has a fourfold contribution to the literature. Firstly, as far as we have reviewed, there are currently very few meta-studies on the nexus under consideration. Secondly, it assesses evidence of publication bias hitherto scantily examined in the finance-growth literature. Thirdly, it identifies fundamental characteristics that genuinely influence the nexus[5]. Fourthly, a corollary to the third contribution is the introduction

---

[4]The hypothesis of Andersen & Tarp (2003) was earlier initiated by Gregorio & Guidotti (1992) who found a negative finance-growth nexus for Latin American countries. This thesis has been partially supported by many authors (Ram, 1999; Luitel & Khan, 1999).

[5] We comprehensively assess whether more than 20 fundamental characteristics in the finance-growth nexus have influenced research outcomes over the past decades: choice of financial development indicators (financial depth:

of financial concepts of money and credit in the meta-examination of the linkage. Hence, we are able to assess whether money or credit matters for the direction of the nexus.

The rest of the paper is organized as follows. Data issues are discussed in Section 2. The empirical analysis and corresponding discussion are covered in Section 3. Section 4 concludes.

2. Data

2.1 Data collection process

Studies used in the meta-study are collected after an extensive search from April to June 2011. ScienceDirect, Econlit, Econpapers, RePEc, Google Scholar and the classical Google search engine are cross-examined for relevant references. Regardless of methodological underpinnings, the base criterion for data collection is the finance-growth nexus. Some papers are discarded due to the absence of empirical analysis with reported student (t) ratios or standard errors. This is the case of causality analysis. Some papers are simply put aside because their English versions could not be found. Of the 186 papers downloaded and examined, only 20 were retained based on the criteria discussed above.

There is yet no clear consensus on the selection process of observations in meta-analysis. While some authors have preferred only one observation per study (Stanley, 2001), others have included all available estimates (Florax et al., 2005). Within the framework of this paper, we follow neither of the two approaches. Whether we collect all the available observations in a given paper depends on the differences in statistical significance. For instance, if a model is used for robustness purposes and corresponding results do not differ significantly from those of the initial model; only one set of observations is collected. This approach has a twofold justification: (1) it mitigates potential issues of overparametization and multicolinearity and; (2) it avoids data selection bias by over-representation of some studies. When a conflict of interest arises, values of

money vs. financial activity: credit); estimation methodology (GMM vs. Least Squares); frequency of data (annual or otherwise)…etc.

the model with the highest coefficient of determination are collected. Consistent with the 'conceptual independence' approach to meta-analysis, we neither reject 'studies examined in different countries with the same methodology' nor 'studies devoted to a specific set of countries with different methodologies'.

Table 1 below summarizes the papers included in the meta-analysis with particular emphasis on the financial intermediary development dynamics encountered in the literature[6]. 196 observations have been collected from the 20 retained studies.

LL: Liquid Liabilities on GDP. PRIVY: Private Credit on GDP. DOMC: Domestic Credit on GDP. PRIVATE: Private Credit on Domestic Credit.

---

[6]At the beginning, we wanted to involve all the financial intermediary development dimensions identified by the Financial Development and Structure Database (FDSD) of the World Bank (WB). These dimensions are consistent with recent finance literature (Asongu, 2013b,c,d,e; Asongu, 2014a,b,c) and include: financial depth (liquid liabilities to GDP); financial allocation efficiency (Bank credit to Bank deposits); financial size (deposit bank assets on central bank assets) and financial activity (private domestic credit to GDP). Unfortunately as we reviewed the literature, we found very scanty evidence of studies that have employed measures of financial allocation efficiency and financial size. Restricting the selection process to financial depth and financial activity, we further discovered that there were three measures of financial activity: ratio of private credit to GDP, ratio of private credit to domestic credit and, ratio of domestic credit to GDP. All the three measures are collected because the last two do not pose any issues of over-representation in terms of degrees of freedom (see Table 1).

2.2 Moderator variables

As shown in Table 2, we control for the unobserved heterogeneity and assess fundamental characteristics that genuinely affect the nexus under meta-investigation. These include: observable financial development dynamics, quality of the dependent variable, the econometric approach, data characteristics, regions and data sources. The choice of the fundamental characteristics is consistent with the motivations of the meta-study. For instance, financial and regional dynamics enable the assessment of the two dimensions of the Andersen & Tarp (2003) hypothesis. Ultimately, more than 20 relevant moderator variables are derived from the 6 fundamental characteristics.

Table 2: List of moderator variables

	Study Characteristics	Moderation variables
1	Financial Development Variables	Liquid Liabilities on GDP Private Credit on GDP Domestic Credit on GDP Private Credit on Domestic Credit
2	Quality of Dependent Variable	GDP Growth (1=GDP, 0=otherwise)
3	Econometric Method	Functional form (1=linear, 0=otherwise), Statistical technique1(1= least squares, 0=otherwise) Statistical technique2 (1=GMM, 0=otherwise) Type of analysis (1=panel, 0=otherwise)
4	Data Characteristics	Frequency of data (1=annual, 0=otherwise) Years (average year of study period) Data transformation 1 (1=log, 0=otherwise) Data transformation 2 (1=variable/GDP, 0=otherwise)
5	Regions	Africa (1=Africa, 0=otherwise) Asia (1=Asia, 0=otherwise) Europe (1=Europe, 0=otherwise) Latin America (1=Latin America, 0=otherwise) North America (1=North America, 0=otherwise) Southeast Asia (1=Southeast Asia, 0=otherwise) Middle East (1=Middle East, 0=otherwise)
6	Data Sources	World Bank (1=Information from the World Bank, 0=otherwise) International Monetary F und (1=IMF information, 0=otherwise) United Nations (1=UN information, 0=otherwise)

GDP: Gross Domestic Product.

3. Empirical Analysis

3.1 Assessing Publication Bias

While we have already highlighted some criteria for the quality of studies in Section 2.1, it is interesting to note that the small sample size which is a standard issue in data collection for this kind of meta-studies has been further compensated with the following criteria in the selection of papers: publication in reputable media, large and more representative samples, control for the potential bias and endogeneity…etc.

Data collection has been based on the following baseline OLS specification[7]

$$y_k = \beta_0 + \beta_1 x_k + \varepsilon_k \tag{1}$$

where y is the dependent variable representing growth[8], x is a measure of financial development and the k subscript represents the number of observations. However, basing our results on Eq. (1) is unfeasible and erroneous because the standard errors (se) and t-statistics are not directly comparable. Hence, the analysis of heterogeneity is typically the first step of data assessment in meta-analysis.

Heterogeneity consists of examining the extent to which beta coefficients in Eq. (1) differ from one another. Accordingly, we convert the estimated coefficients into their partial correlations. Owing to their unitless characteristics, partial correlations are ideal for comparing the finance-growth linkage across the literature under consideration. Consistent with the meta-analysis literature (Doucouliagos et al., 2012; Stanley & Doucouliagos, 2012), the partial correlations (r) are computed from the t-statistics (t) and degrees of freedom (df) as shown in Eq. (2) below:

---

[7] While Ordinary Least Squares (OLS) has been used in meta-analysis (see Card & Krueger, 1995; Görg & Strol, 2001; Havranek & Irsova, 2010), the predominant estimation technique is weighted least squares.
[8] The dependent variable in Equation 1 is first converted into partial correlations based on Equation 2 to obtain unitless characteristics. Then the partial correlations are divided by the corresponding standard errors (see Eqs 5-6).

$$r = \frac{t}{\sqrt{(t^2 + df)}} \qquad\qquad (2)$$

A consistent bulk of the empirical literature examining the finance-growth nexus is characterized by substantial distortions in the magnitude of estimated effects, especially when studies report estimates toward a specific value. Hence, the possibility of selection or publication bias[9]. In accordance with the meta-analysis literature, failing to take this publication bias issue into account may lead to overstating the magnitude of the genuine effect.

3.1.1 A simple graphical test

As shown in Figure 1 below, a scatter plot is presented to test for publication bias. Accordingly, a funnel-like symmetrical representation denotes the absence of publications bias. In the figure, while the horizontal axis presents the partial correlations of the estimated coefficients, the vertical axis shows the measurement of the precision. The most common measure of precision is the inverse of the standard error (INSE). The absence of the bias under consideration implies that the estimated effects are distributed symmetrically around the genuine effect or around zero when no genuine effect exists. Normally, studies with large (small) sample should result to more (less) precise estimates, implying smaller (larger) standard errors. Hence, less precise estimates at the bottom of the graph ought to be spread out more than precise ones at the top of the graph. Consequently in the absence of bias, a scatter plot should resemble a symmetric funnel.

---

[9] The "file drawer" problem occurs when researchers publish exclusively studies with significant results that are in line with mainstream theory because these findings have a high probability of being accepted for publication in academic journals. Therefore studies with a limited likelihood of publication are simply "filed" and kept in the "drawer". Mainstream studies on meta-analysis have consistently underlined this issue (Card & Krueger, 1995; Görg & Strobl, 2001; Mookerjee, 2006).
Figure 1: Funnel plot

From Figure 1 above, it could clearly be seen that the positive effects are over-reported which confirms the presence of a positive-effect bias. However, it should be noted that the funnel plot provides only indications and not definite evidence. Therefore, the positive-publication bias may be attributed to other factors. It is thus important to assess bias beyond diagrammatic representations.

3.1.2 Funnel Asymmetry test

The most documented formal analysis for publication bias is the "Funnel Asymmetry Test" (FAT) developed by Stanley (2008) from Egger al. (1997). The test is based on the following regression:

$$c_k = \beta_0 + \beta_1 se_k + \eta_k \qquad (3)$$

where c stands for the estimated coefficient of the financial development variable on growth and, *se* are the standard errors corresponding to the estimated coefficients. In the absence of bias in the finance-growth literature, the estimated effects are not related to the corresponding standard errors. Testing for the significance of the constant term is traditionally regarded as the Precision Effect Test (PET) because the effects should be randomly distributed around the

(constant). Accordingly, the estimated coefficient corresponding to the standard errors should tend toward zero as the size of the sample increases. Hence, a significant effect of the coefficient corresponding to the standard errors is evidence of publication bias.

Inferences based on FAT are invalid because the estimated effects collected from the finance-growth nexus literature are not directly comparable. An issue which can be addressed with the use of partial correlations and corresponding standard errors:

$$r_k = \beta_0 + \beta_1 se_k + \mu_k \qquad (4)$$

where r is the partial correlation of the estimated effect of c, se is the corresponding standard error of r and u is the error term. Unfortunately, Eqs. (3) and (4) suffer from heteroscedasticity. To avoid misleading inferences, we divide the Eq. (4) with the corresponding standard errors. Hence the new equation becomes:

$$r_k^* = \beta_1 + \beta_0 \frac{1}{se_k} + \upsilon_k \qquad (5)$$

The asterisk on the dependent variable means that the ratios (partial correlations) have been divided by the corresponding standard errors. This slight modification does not change the inference because; there is still a constant effect and a genuine effect. Since estimation by simple OLS could lead to biased estimates due to potential correlation among estimates within one study, we also estimate with cluster robust (CR) standard errors as reported in Table 3 below.

Table 3 : Funnel Asymmetry Test

	Intercept (β_1)	1/SEr (β_0)	Adjusted R²	Fisher	Studies (j)	Obs (n)	Testing $\sigma_\varepsilon^2 \leq 2$
OLS	**12.957*** (0.000)**	**-0.143*** (0.000)**	0.206	**51.849*** (0.000)**	20	196	P-value (0.000)
OLS-CR	**12.957*** (0.000)**	-0.143 (0.130)	0.206	2.305 (0.130)	20	196	P-value (0.000)

OLS: Ordinary Least Squares. CR: Cluster Robust. Obs: observations. *P-values* in brackets.

Table 3 above shows findings of the FAT. The results broadly indicate the presence of publication bias because the intercept is statistically significant in both specifications. As we

11

move from the OLS to the OLS-CR specification, evidence of the genuine effect disappears. However the finding at this level is not definite because previous research has shown that, in cases with unexplained heterogeneity, FAT and PET results may be misleading (Stanley, 2008). We justify the presence of unexplained heterogeneity by testing the hypothesis that the variance of the error term is less or equal to 2 (see last column). The null hypothesis for the absence of unexplained heterogeneity is strongly rejected. Hence, the need to control for this unexplained heterogeneity using moderation variables in a meta-regression analysis.

3. 2 Meta-analysis

The purpose of the meta-analysis is to reveal the specific factors that affect the reported values. While some factors may contribute to publication bias, others contribute to the genuine effect. Since factors accounting for publication bias are by nature highly correlated with those contributing to the genuine effect, we limit moderator variables to the latter effect for three main reasons: (1) we have already substantially covered the issue of publication bias; (2) the genuine effect of finance-specific factors is consistent with the motivation of the study and; (3) in accordance with the conclusion of the previous section, the moderator variables for the genuine effect are used to explained the unobserved heterogeneity. The choice of the moderator variables has already been substantially documented in the data section. Eq (6) below shows how Eq. (5) is adjusted to included the moderator variables (M_{ik}).

$$r_k^* = \beta_1 + \beta_0 \frac{1}{se_k} + \sum_{k=1}^{K} \gamma_k M_{ik} \frac{1}{se_k} + \upsilon_k \qquad (6)$$

The findings in Table 4 below are based on Eq. (6) above. The use of two specifications has a twofold justification: on the one hand, it enables us to mitigate the three main issues of overparametization and multicolinearity (see bold figures of the correlation analysis in Appendix 1); on the other hand, it is a means of robustness check. From the cluster robust OLS

12

estimations, the following findings can be established. (1) The significant intercept indicates evidence of publication bias whereas the significant estimate corresponding to the '1/se' beta variable shows evidence of a genuine effect. (2) The incorporation of financial depth (liquid liabilities) and domestic credit influence a larger effect on the finance-growth nexus while the addition of private credit (in GDP or domestic credit terms) is favorable to a smaller effect on the finance-growth nexus. (3) While the use of OLS may lead to higher effects, when the issue of endogeneity is addressed (with GMM), the nexus is of a lower effect. (4) Data transformation in logarithm (ratio of GDP) significantly influences a higher (lower) relationship. (5) With the exception of North America and slight exception of Europe, the inclusion of Asian, South East Asian and Middle East countries also significantly improve the partial coefficient correlations. (6) Data from the World Bank increases the possibility of a larger effect; that from the IMF is favorable to a lower effect. Conversely data from the UN has not effect.

3.3 Further discussion of results

We now devote more space to discussing the position of the thesis of positive spillovers of financial services on growth. This discussion will be categorized in two strands: an empirical explanation and a historical perspective.

Three points are worth discussing from the empirical perspective: endogeneity-based evidence, the relevance of publication bias and genuine effects of the finance moderator variables. Firstly, we have noticed that, estimation techniques (GMM) that take the endogeneity concern into account lead to results with smaller effects in the finance-growth nexus and those (OLS for instance) that do not take it into account are favorable to larger effects in the finance-growth nexus. Secondly, as we have already seen above, there is substantial evidence of publication bias in which insignificant (or negative) finance-growth nexus papers are simply not sent out for publication because of their low probabilities of being accepted in academic journals.

It follows that many manuscripts that have not met some criteria of the mainstream finance-growth conception have substantially suffered from the 'file drawer' problem and are unrepresented in the literature. Thirdly, based on the genuine effects of the selected financial variables, we have observed that financial activity (private domestic credit) genuinely decreases evidence of larger effects in the finance-growth nexus. Financial depth (liquid liabilities) that reflects a larger effect in the nexus is not as important as financial activity because the former is a simple measure of financial system deposits or an extensive use of currency (Money Supply) that may not necessarily transit via the banking sector (in developing countries).

From a historical perspective, it is important to first of all recall that proponents of a smaller effect in the finance-growth nexus have sustained that financial development greatly penalizes economic growth in periods of financial meltdown. Therefore the determining threshold remains the trade-off between financial instability and financial development in economic growth (Kaminsky & Reinhart, 1999; Demirguc-Kunt & Detragiache, 1998). With this interesting background, it could be inferred that in the early 20th century (of Schumpeter's time)[10] the lower effect of financial instability on economic growth was less severe than what we are currently witnessing today. To put this fact into perspective: "*the modern era of globalization has been associated with significant economic transformation around the world, but also an increasing frequency of financial crises. According to Eichengreen and Bordo (2002) there were 39 national or international financial crises between 1945 and 1973. Their frequency increased from 139 between 1973 and 1997, culminating in the Asian financial crisis*" (Buckle, p.36). The argument can further be buttressed by the evidence that characteristics of financial crisis run counter to the mainstream thesis. The presence of financial instability decreases favorable macroeconomic conditions for a strong economic growth: easy mobilization of productive

---

[10] Schumpeter, J. (1911). The Theory of Economic Development, Cambridge, MA, Havard University Press.

savings, efficient resource allocation, reduction of information asymmetry and, improvement of risk management.

4. Conclusion

In a meta-study on the finance-growth nexus, we have bridged the gap between the pros and cons of a questionable finance-growth nexus. Over 20 fundamental characteristics that have influenced the debate over the last decades have been examined. The empirical evidence is based on 196 outcomes from 20 studies. We have assessed the degree of heterogeneity and identified causes of the observed differentiation. Our findings also show evidence of publication bias. Overall, a genuine effect exists between financial development and economic growth. The appealing thesis of strong positive finance-growth nexus might be less relevant in our era because of: endogeneity-based estimations, publication bias and, effects of financial activity. A historical justification has also been discussed.

As a policy implication, encouraging the publication of results with findings that are not consistent with the mainstream positive finance-growth nexus should provide new scholarly insights into the relationship. Consistent with Asongu (2014a), depending on the specific context of sampled countries, the role of policy has also been to encourage financial development through measures that may expose countries to negative external shocks like financial crises. Policy makers that have been viewing the challenges of development exclusively from this point of view for the rewards of growth may not be getting the financial dynamics correctly.
