ABSTRACT

This paper assesses the empirical desirability of the East Asian economies to an alternative exchange rate arrangement (a monetary union) that can potentially enhance the exchange rate stability and credibility in the region. Specifically, the symmetry in macroeconomic disturbances of the East Asian economies is examined as satisfying one of the preconditions for forming an Optimum Currency Area (OCA). We extend the existing literature by improving the methodology of assessing the symmetry shocks in evaluating the suitability of a common currency area in the East Asian economies employing the Bayesian State-Space Based approach. We consider a model of an economy in which the output is influenced by global, regional and country-specific shocks. The importance of a common regional shock would provide a case for a regional common currency. This model allows us to examine regional and country-specific cycles simultaneously with the world business cycle. The importance of the shocks decomposition is that studying a subset of countries can lead one to believe that observed co-movement is particular to that subset of countries when it in fact is common to a much larger group of countries. In addition, the understanding of the sources of international economic fluctuations is important for making policy decisions. Our findings also indicate that regional factors play a minor role in explaining output variation in the East Asian economies. Based on the insignificant share of regional common factor, our results imply that East Asia does not satisfy the OCA criteria.

1. INTRODUCTION

East Asia was late in jumping onto the regionalism bandwagon in comparison with the European and North American countries. The first Regional Trade Arrangements in East Asia only existed in 1977 when Association of Southeast Asian Nations (ASEAN)¹ reached an agreement on its Preferential Trading Arrangements. Several further attempts to forge closer economic integration amongst the East Asian countries during the 1990s were unsuccessful. Most researchers identified three major reasons for the sudden interest in East Asia for greater economic integration: (1) the failure of the World Trade Organization (WTO) and Asia-Pacific Economic Cooperation (APEC) to make any significant headway on trade liberalization. (2) the widening and deepening economic integration in Europe and North America; and (3) the Asian Financial crisis.

East Asian countries have reassessed their strategies towards further trade liberalization after the failure to launch a new round of trade negotiations during the WTO Ministerial Meeting in Seattle. If the global trading system does not continue to liberalize, the region may be affected negatively as many of the East Asian countries depend on export to sustain their economic growth.² Hence, the perception that a new round of WTO trade negotiations had failed to materialize due to a lack of enthusiasm and political will in both the US and Europe has fueled concerns among the East Asian countries about the direction that the global trading system is heading. In Europe, the European Union (EU) has expanded into Central and Eastern Europe and will be progressing into greater monetary union. In the United States (US), North American Free Trade Area (NAFTA) and Latin American countries are heading towards greater economic integration.

On the monetary side, the single greatest push for East Asian regionalism was Asian crisis, sparked in mid-1997 by the devaluation of the Thai baht, and the related global financial crisis, triggered by the Russian debt default in August 1998, shook the foundations of the international monetary system. Many East Asian countries felt that they were let down by the West during the crisis. In their view, western banks and other financial institutions had created and exacerbated the crisis by pulling out their funds from the region. The leading financial powers then either declined to take part in the rescue operations (as was the case of US with Thailand) or built in excessively stringent demands into their financial assistance programs. At the same time, there was a negative perception among East Asian countries that the International Monetary Fund (IMF) and the US were dictating their policy responses to the crisis by controlling their access to funds and private capital markets (Yip, 2001). This resentment was further fuelled by the widespread view that the IMF's rescue programs had worsened the situation for the East Asian economies by pushing them into a deeper economic recession than was necessary to begin with (Bergsten, 2000). Whether these views were justified, the East Asian countries have decided that they do not want to be beholden to the West should a crisis recur in the future (Yip, 2001). The idea of a common currency for APT became popular after the Asian Financial Crisis 1997. Currency stability was identified as

¹ Comprising only the founding members: Indonesia, Malaysia, the Philippines, Singapore and Thailand.

² Bergsten (2000).

important to avoiding future financial crises and greater monetary and exchange rate cooperation is called for in the Chiang Mai Initiative 2000 in Thailand.

After the Chiang Mai Initiative in 2000 that established a regional currency-swap facility, the idea of a single currency for East Asia was created. There are also efforts beyond the Chiang Mai Initiative to coordinate macroeconomic and exchange rate policies. An ASEAN Task Force on ASEAN Currency an Exchange Rate Mechanism was established in March 2001.³ In addition, the Kobe Research Project is conducted to provide stimulus to this work through studies exploring ways and means to improve regional monetary and financial cooperation. Although the progress and commitment in monetary cooperation in East Asia has been encouraging, much remains to be accomplished.

Robert Mundell's OCA theory has been widely used to assess the suitability of the EU to form a monetary union. Although there has been increasing interest among the researchers to examine the suitability of East Asian countries for a common regional currency, most of the related studies have been based primarily on inappropriate econometrics techniques. Simple correlation between countries is mainly used to measure the degree of shock symmetry in the OCA literature. The correlation is usually calculated between a country and a chosen anchor country. Lee *et al.* (2002) provided some disadvantages of bilateral measures in the following reasons: (1) the degree of region-wide co-movements, rather than bilateral ones provides a more appropriate measure since we are interested in the net benefits of adopting a common monetary policy across economies in the region; (2) the simple correlation does not offer the sources of the shocks, there may be the third factor such as the world common shocks that induce a high correlation between countries; (3) there is no single country plausibly offers a regional anchor.⁴

Another celebrated technique in OCA literature is Bayoumi's structural VAR technique. The first stage of this technique consists of running a national VAR of changes of output and prices. To identify the coefficients of the structural form, Bayoumi assumed the orthogonality of supply and demand shocks that only supply shocks are able to affect the level of output, and that demand shocks are temporary. This approach comes with several caveats. First of all, if the logs of output and prices in quarterly format are cointegrated in several of the countries of the sample, the coefficients of the VAR are asymptotically biased. In addition, as Bayoumi recognizes, neither the orthogonality of supply and demand shocks nor the short duration of demand shocks are uncontested assumptions. A shock to terms of trade would affect both aggregate supply and demand. In economies with high unemployment rates, demand shocks can be expected to have effects that are highly persistent, if not permanent. Bayoumi and Eichengreen (1994) argued that only supply shocks are crucial disturbances to which independent monetary policy wishes to respond. Many researchers see little justification that only supply shocks matter.⁵ They argue that

³ The Task Force completed the study in September 2002 and it was presented at the meeting of the ASEAN Central Bank and Finance Deputies in Myanmar in October 2002.

⁴ In Europe, Germany is generally perceived as the regional anchor. In East Asia, however, there is no country which can play such similar role.

⁵ Among others, see Lee *et al.* (2002).

there may not be much room left for the policy makers to react to if supply shocks are permanent shocks. In addition, if demand shocks do not originate from policy implementations, the monetary policy authority may wish to counteract to these disturbances. The existing methodologies also fail to recognize the sources of the shocks. For instance, one does not know whether the economic fluctuations of a country are accounted by the country specific, regional or the world common factors.

In the business cycle literature, there exists a strand of methodology that allows the analysis at a disaggregated level using the Bayesian State-Space Model. However, such methodology is mainly used to analyze the business cycles in the Western countries. Very few, to our knowledge, have applied it in the OCA context. We propose to employ this model which allows us to decompose aggregate shocks into country-specific, regional and world common business cycles. The importance of studying all three in one model is that studying a subset of countries can lead one to believe that observed co-movement is particular to that subset of countries when it in fact is common to a much larger group of countries. For example, Kose *et al.* (2003) find that the distinct “European” business cycle in the European countries is due to co-movement common to all countries in the world. Understanding the sources of international economic fluctuations is important for making policy decisions. For example, if a country exhibits a large value of the share accounted by the region common factor, then its business cycle movement is largely synchronized to the region, indicating that a regional common monetary policy is more effective to respond to the disturbances. However, if a country possesses a smaller value of the share accounted for by the region common factor and a larger value of that accounted for by the country-specific factor, it needs to rely more heavily on its own independent counter-cyclical monetary policy. Unlike previous studies that examine only the degree of correlations of business cycle among countries, our study enables us to identify the sources of the economic fluctuations for each country. As a result, composition of the shocks in East Asia will be identified and appropriate policy actions can be undertaken accordingly.

2. LITERATURE REVIEW

The symmetry of underlying shocks among the East Asian countries provides one of the preliminary guides in identifying potential members for monetary union. The rationale is that countries experiencing similar disturbances are likely to respond with similar policies, thus making them better candidates for forming a monetary union. The estimation of the incidences of macroeconomic disturbances is inherently empirical. One of the first empirical papers to have dealt with the issue of macroeconomic disturbances through a statistical approach is by Bayoumi and Eichengreen (1993, 1994). Applying a variant of the VAR methodology proposed by Blanchard and Quah (1989), Bayoumi and Eichengreen (1993) assessed the nature of macroeconomic disturbances among different groups of countries. Bayoumi and Eichengreen (1994) showed that supply shocks are symmetrical among (1)

Japan, South Korea and Taiwan and (2) Hong Kong, Indonesia, Malaysia and Singapore.⁶ Demand shocks are found to be highly symmetrical for the latter group of countries. Based on the OCA criterion of symmetry in underlying disturbances, they conclude that these two groups of countries are likely to form separate OCAs. Their results on the correlation, size and speed of adjustment to underlying disturbances for Asia are updated in Bayoumi, and Mauro (1999).⁷ It is concluded that aggregate supply disturbances affecting Indonesia, Malaysia and Singapore are reasonably correlated, while the Philippines and Thailand experience more idiosyncratic shocks.⁸ Their study also reports that, (1) size of the disturbances experienced by the Asian economies is considerably larger than that of the equivalent shocks for Europe⁹; (2) the speed of adjustment in Asia (and ASEAN in particular) is much more rapid than in Europe. Based on economic criteria, the authors conclude that ASEAN is less suitable for a currency union than the continental European countries were in 1987 (a few years before the Maastricht treaty providing a road map for EMU was signed), although the difference is not very large.¹⁰

Using a different methodology from Bayoumi and Eichengreen (1994), Wyplosz (2001) identifies shocks as the residuals from simple AR(2) regressions of real GDP for the Asian, European, Australia and New Zealand countries using annual data over the period 1961-1998.¹¹ He finds that shocks in European countries are significantly more correlated than shocks in Asian countries.¹² It is reported that Korea, Malaysia and Thailand seem to be more correlated with Japan. As recognized by the author, the difference between his results and Bayoumi-Eichengreen's (1994) results can be due to the different methodology or to the sample period (Bayoumi and Eichengreen's sample covers from 1972 to 1989).¹³ Most empirical analyses based on the theory of optimum currency areas, including those of Taguchi, and Bayoumi and Eichengreen (1994) and Wyplosz (2001) cited above, have focused on the costs of monetary integration and studied the correlation of various macroeconomic variables among the Asian countries. In an effort to combine the various criteria for a monetary union, Bayoumi and Eichengreen (1999) developed an "OCA index" that predicts the expected level of exchange rate variability for various Asian countries.¹⁴ They derive the index from the results of a cross-sectional regression covering advanced and East Asian economies that relates observed exchange rate variability to four optimum currency indicators. The independent variables are: (i) the standard deviation of the difference in growth rates across the two economies; (ii) the dissimilarity of the composition

⁶ Bayoumi and Mauro (1999) argue that aggregate supply disturbances are generally more relevant than aggregate demand disturbances, because aggregate supply disturbances are more related to private sector behavior rather than the impact of macroeconomic policies.

⁷ The updated Asian results use data from 1968 to 1998, compared to a sample period of 1969-1989 used in the European results reported.

⁸ The authors claim that there are parallels with Europe, where the shocks experienced by France and Germany are relatively highly correlated, while those affecting Italy and Spain were more idiosyncratic.

⁹ This also occurs when the sample period excludes the Asian crisis (1997 and 1998).

¹⁰ The authors view firm political commitment as vital in forming a regional currency arrangement.

¹¹ The Asian countries under study include: China, Hong Kong, Indonesia, Japan, Korea, Malaysia, the Philippines, Singapore, Taiwan and Thailand.

¹² Since the author also find that trade integration is deeper in Asia than it is in Europe, it can be concluded that a high degree of trade integration does not translate into strong output correlations.

¹³ Bayoumi and Eichengreen (1994) find little difference between Europe and Asia for both supply and demand shocks. Besides, different country groupings are identified.

¹⁴ The East Asian countries are Japan, Hong Kong, Korea, Singapore, Taiwan, Indonesia, Malaysia, the Philippines and Thailand (covering the sample period from 1976 to 1995).

of trade; (iii) the level of bilateral trade; and (iv) the size of the two economies. The first two indicators are proxies for the costs associated with asymmetric shocks, the second two for the benefits from stabilizing exchange rates with close trading partners and across larger groupings. Based on the OCA index, the authors report that the following country pairs achieve scores comparable to those in Western Europe: Singapore-Malaysia, Singapore-Thailand, Singapore-Hong Kong, Singapore-Taiwan, and Hong Kong-Taiwan.¹⁵ However, Indonesia, South Korea and the Philippines do not rank well, and the Malaysia-Thailand pair displays a very weak score.

Recently, Bacha (2008) employs a Vector Autoregression Model and Correlation Analysis to examine the common linkages among 14 East Asian countries. The results show an absence of broad-based common linkages but suggest the following several paired clusters: Malaysia-Singapore; Japan-Korea; Indonesia-Thailand; Australia-New Zealand. His findings of paired clusters are consistent with the findings of Hazel (2001)¹⁶ and Sato and Zhang (2006)¹⁷. Bacha (2008) suggest that geographic proximity may be the reason behind the results.

3. METHODOLOGY

The econometric model employed here follows the dynamic unobserved factor model in Kose *et al.* 2003), which is an extension of the single dynamic unobserved factor model in Otrok and Whiteman (1998). The world economy consists of many different regions and each region consists of many different countries. This study decomposes the movement of an aggregate output, consumption, and investment in each country *i* into four different components: (i) the world common component, (ii) the region common component and (iii) the country-specific component and (iv) idiosyncratic component specific to each time series.. Every country in the world is influenced by the world common, while the region common component influences only the countries belonging to the same region. The influence of country-specific component is restricted to the specific country. For example, the output of Malaysia fluctuates due to shocks to the world economy, shocks to the East Asian region or Malaysia-specific shocks.

We should recognize that it is not a threshold question that East Asia's business cycle synchronization must pass a certain value in order to satisfy the OCA criteria. In fact, there are no exact empirical standards set for the OCA criteria and researchers can only make their own judgments based on the empirical results. The Euro Area, the first region in the world to adopt a single currency, should be used as the benchmark for any regions who are interested to form a monetary union. In this paper, the benchmarks of the comparison are the European Union and the North American countries.¹⁸

¹⁵ These are the cases where the value of the OCA index approaches Western European levels.

¹⁶ Hazel (2001) suggests the paired clusters of Malaysia/Singapore, Japan/Korea and Hong Kong/Taiwan.

¹⁷ The authors found short-run common business cycles in Singapore, Thailand and Indonesia; Hong Kong, Korea and Mainland China; Japan and Taiwan.

¹⁸ Refer to the Appendix for a list of the countries in these regions.

In our model, there are K dynamic, unobserved factors thought to characterize the temporal co-movement in the cross-country panel of economic time series. Let $Y_{i,t}$ denote the observable variables (output, consumption and investment) at time t for country i , N denote the number of countries, M the number of time series per country, and T the length of the time series. The $Y_{i,t}$ series for each country is decomposed into three separate components:

$$Y_{i,t} = a_i + b_{wi} Y_t^W + b_{ri} Y_t^R + b_{ni} Y_t^N + \varepsilon_{i,t} \quad (1)$$

$$E \varepsilon_{i,t} \varepsilon_{j,t-s} = 0 \text{ for } i \neq j$$

Let Y_t^W (world common factor) be an unobservable component of world economic activity common to all the countries; Y_t^R (region common factor) be an unobservable component common to each country belonging to the same region R and Y_t^N be an unobservable component of country specific factors. There are three regions considered: East Asia, Europe and North America areas. If $R = 1$, that country belongs to East Asia, if $R = 2$, it belongs to the Europe, and if $R = 3$, it belongs to North America.

The coefficients, b_{wi} , b_{ri} and b_{ni} are the impact coefficients on factors Y_t^W , Y_t^R and Y_t^N , reflecting the degree to which variation in y_i can be explained by each factor. The impact coefficients are allowed to differ across countries since the world common and the region common factors have different influences on each country. There are $M \times N$ time series to be “explained” by the (many fewer) $N+R+1$ factors. The “unexplained” idiosyncratic errors $\varepsilon_{i,t}$ are assumed to be normally distributed, but may be serially correlated and are modeled as p_i -order autoregressions:

$$\phi_i(L) \varepsilon_{i,t} = u_{i,t} \quad (2)$$

or
$$\phi_i(L) = 1 - \phi_{i,1}L - \phi_{i,2}L^2 - \dots - \phi_{i,p_i}L^{p_i}$$

is a polynomial in the lag operator L ; $E u_{i,t} u_{j,t-s} = \sigma_i^2$ for $i = j$ and $s = 0$, 0 otherwise.

The evolution of the unobserved factors is likewise governed by an autoregression of q_i -order with normal errors:

$$f_{k,t} = \varepsilon_{f_k,t} \quad (3)$$

$$\varepsilon_{f_k,t} = \phi_{f_k,1} \varepsilon_{f_k,t-1} + \phi_{f_k,2} \varepsilon_{f_k,t-2} + \dots + \phi_{f_k,q_k} \varepsilon_{f_k,t-q_k} + u_{f_k,t} \quad (4)$$

$$E u_{f_k,t} u_{f_k,t-s} = \sigma_{f_k}^2 \text{ for } s = 0; 0 \text{ otherwise}$$

$$E u_{f_k,t} u_{i,t-s} = 0 \text{ for all } k, i \text{ and } s.$$

As in Otrok and Whiteman (1998), all the innovations, $u_{i,t}$, $i = 0, \dots, M \times N$ and $u_{f_k,t}$, $k = 1, \dots, K$ are assumed to be zero mean, contemporaneously uncorrelated normal random variables; that is $u_{i,t} \sim N(0, \sigma_i^2)$ and $u_{f_k,t} \sim N(0, \sigma_{f_k}^2)$. Thus all co-movement is mediated by the factors, which in turn all have autoregressive representations (of possibly different orders).

There are two related identification problems arise for the model¹⁹ (1)-(4): the signs and the scales of the dynamic factors (Y_t^W , Y_t^R and Y_t^N) and the impact coefficients (b_{wi} , b_{ri} and b_{ni}) cannot be separately identified. Following Otrok and Whiteman (1998), signs are identified by requiring one of the impact coefficients to be positive for each of the factors. In particular, b_{wi} (impact coefficient for the world factor) for the US output; country factors are identified by positive impact coefficients for output for each country, and the regional factors are identified by positive coefficients for the output of US for the North America region; Germany for the Europe region; and Singapore for the East Asian region.²⁰ Scales are identified following Sargent and Sims (1977) and Stock and Watson (1989, 1992, and 1993) by assuming that each $\sigma_{f_k}^2$ is equal to a constant.

However, the dynamic factors (Y_t^W , Y_t^R and Y_t^N) are unobservable, traditional methods cannot be employed and special methods must be used to estimate the model. Gregory *et al.* (1997) follow Stock and Watson (1989, 1992 and 1993), using classical statistical techniques employing the Kalman filter for estimation of the model parameters, and the Kalman smoother to extract an estimate of the unobserved factor. They treat a related model as an observer system. Otrok and Whiteman (1998) used an alternative model based on a recent development in the Bayesian literature on missing data problems called “data augmentation” (Tanner and Wong, 1987).

Under a conjugate prior, the model (1)-(4) would be a simple set of regressions with Gaussian autoregressive errors if the factors were observable. This structure can be used to determine the conditional (normal) distribution of the factors given the data and the parameters of the model. It is then straightforward to generate random samples from this conditional distribution. These samples will then be used as stand-ins for the unobserved factors. The essential idea is to determine posterior distributions of all unknown parameters conditional on the latent factor, and then if the conditional distribution of the latent factor given the observables and the other parameters is available, the joint posterior distribution of the unknown parameters and the unobserved factor can be sampled using a *Markov Chain Monte Carlo (MCMC)* procedure on the full set of conditional distributions.

We start sampling by taking starting values of the parameters and factors as given and follow the following steps:

- (i) Sample from the posterior distribution of the parameters conditional on the factors;
- (ii) Sample from the distribution of the world factor conditional on the parameters and the country and regional factors;
- (iii) Sample each regional factor conditional on the world factor and the country factors in that region;

¹⁹ These problems are also recognized by Otrok and Whiteman (1998) and Kose *et al.* (2003).

²⁰ In Kose *et al.* (2003), regional factors are identified by positive coefficients for the output of US for the North America region; Cameroon for the Africa region; Costa Rica for the South America region; France for the Europe region, Bangladesh for the Asia (poor) region; Hong Kong for the Asia (rich) region and Australia for the Oceania region.

- (iv) One step of the Markov Chain is completed by sampling each country factor conditioning on the world factor and the appropriate regional factor.²¹

This sequential sampling of the full set of conditional distributions is known as “Gibbs sampling” (See Chib and Greenberg, 1996; Geweke, 1997). Technically, our procedure is “Metropolis within Gibbs” (Kose *et al.*, 2003), as one of the conditional distributions – for the autoregressive parameters given everything else – cannot be sampled from directly. As in Otrok and Whiteman (1998) and Kose *et al.* (2003), we follow Chib and Greenberg (1996) in employing a “Metropolis-Hastings” procedure for that block. Given the bounded likelihood and proper priors that are used in the model, the joint posterior is well behaved, and thus the regularity conditions of Geweke (1997), Tierney (1994), and Chib and Greenberg (1996) apply, and the procedure produces a realization of a Markov chain whose invariant distribution is the joint posterior of interest.

Let φ denote the set of parameters $(a_i, b_{wi}, b_{ri}, b_{ni}, \sigma_i^2, \phi_{ij}) i = 1, \dots, n$. We then proceed in the following two steps:

- (i) Describe analysis of the posterior of φ conditional on the dynamic factors by applying Chib and Greenberg’s (1994) procedure in estimating regression models with AR errors.
- (ii) Determination and analysis of the conditional distribution of the factors given φ using Otrok and Whiteman’s (1998) procedure.

The length of both the idiosyncratic and factor AR polynomials is 3.²² The priors used in this paper are quite standard. Following Kose *et al.* (2003, 2008), the prior on all the factor loading coefficients is Normal with mean zero and precision equal to one. The prior for the idiosyncratic innovation variance σ_i^2 is an Inverted Gamma (6, 0.001), which is quite diffuse. The priors for the AR polynomials parameters are Normal with mean zero and precision equal to one for the first lag, 0.5 for the second lag and 0.25 for the third lag. Since the data are in log-difference, this prior represents the idea that growth is not serially correlated and the certainty that lags are zero grows with the length of the lag. The stationarity of the lag polynomial is ensured by drawing from a truncated normal distribution in the MH step.²³ The usage of tighter and looser priors for both the factor loadings and the AR parameters produce little changes to the results.

Following Kose *et al.* (2003), we measure the relative contributions of the world, region, and country factors to variations in aggregate output in each country by estimating the share of the variance of the output aggregate due to each factor. Since the world common, the region common, and the country-specific factors are orthogonal, the variance of aggregate output for country i can be decomposed into:

$$\text{Var}(Y_{i,t}) = (b_{wi})^2 \text{Var}(Y_i^W) + (b_{ri})^2 \text{Var}(Y_i^R) + (b_{ni})^2 \text{Var}(Y_i^N) + \text{Var}(\varepsilon_{i,t})$$

²¹ Note that the sampling order within each step is irrelevant. Kose *et al.* (2003) experimented with changing the order, and the results obtained were indifferent.

Models with different lag lengths are compared and the lag length which yields the highest marginal likelihood is chosen. Kose *et al.* (2003, 2008) chose the same length of both the idiosyncratic and factor AR polynomials in their studies.

²³ See Otrok and Whiteman (1998) for the discussion.

Let s_i^f denote the share of the variance of aggregate output for country i accounted for by variation in the factor $f = W, R, N$.

$$S_i^f = \frac{(b_{fi})^2 \text{Var}(Y_t^f)}{\text{Var}(Y_{i,t})}$$

These measures can be calculated at each pass of the Markov chain. The estimates of the shares accounted for by the world common, the region common and the country-specific factors will play a crucial role in evaluating if countries belonging to the same region are eligible to form a regional currency arrangement. Especially a large value of the share accounted for by the region common factor – capturing how symmetric shocks are within a region – constitutes a *prima facie* case for a currency union.

4. RESULTS AND ESTIMATION

We first examine the reliability of the estimated results using the Markov Chain Monte Carlo (*MCMC*) diagnostics. We employ such commonly used diagnostics as the numerical standard error (*NSE*), convergence diagnostic (*CD*), estimated potential scale reduction and the highest potential density intervals (*HPDI*). We employ James Lesage's Econometrics Toolbox (Lesage, 1999) using *MATLAB* program. We have passed all the above mentioned convergence diagnostics, confirming that the posterior simulators are working well and the number of draws is sufficient to achieve the desired degree of accuracy. The results of these *MCMC* diagnostics are reported in Table 1 to Table 7 in the Appendix. The test for heteroscedasticity is also conducted to examine if the error variances differ across observations. We employ the test for heteroscedasticity developed by Bauwens and Lubrano (1991).²⁴ The properties of Bayesian residuals and the diagnostic procedures are discussed in Bauwens *et al.* (1999). The results presented in Table 8 in the Appendix show that the presence of heteroscedasticity is not detected in the model.²⁵

This study examines eight East Asian countries, namely ASEAN 5 – Indonesia, Malaysia, the Philippines, Singapore and Thailand – and China, Japan and Korea.²⁶ The list of 17 European and 3 North American countries included in the study is provided in the Appendix (Table 9). The data used in this paper are drawn from the Penn World Table, the sample period is from 1970 to 2000.²⁷ All series (real GDP, consumption and investment) are log-differenced. Gauss program is used in the estimation. It can be shown that the accuracy of the model estimation gets better and better as the number of replications is increased. We found convergence after 50,000 draws. The reported results here are based on 100,000 draws

²⁴ Luc Bauwens has generously supplied us with the Gauss codes for the testing heteroscedasticity.

²⁵ Among others, the Bayesian model with heteroscedasticity can be estimated using the *GAUSS* program. The *Gauss* codes are provided in Luc Bauwens' website that accompanied the book Bauwens *et al.* (1999).

²⁶ The new ASEAN members include Cambodia, Laos, Myanmar and Vietnam are excluded in the study as the stages of development in these countries are very much different from the rest of the East Asian countries. Williamson (1999), for example, omits the new members of ASEAN, limiting the heterogeneity of the countries adopting a common basket peg. We lack data on Brunei.

²⁷ It is our intention to examine the business cycle synchronization for the European countries before the adoption of Euro.

with 10,000 burn-in replications. We report the variance shares (medians, 33 per cent and 67 per cent quantiles of posterior) attributable to the world, regional and country factors for East Asia, Europe and North America in Tables 10.²⁸

Table 10: Variance Decompositions (Regional Average)

East Asia			
	1/3	Med	2/3
World	6.86	8.07	9.39
Country	60.97	64.83	68.40
Region	1.28	3.11	6.31
Europe			
	1/3	Med	2/3
World	26.53	28.80	31.11
Country	18.80	23.04	27.44
Region	1.31	2.61	4.69
North America			
	1/3	Med	2/3
World	16.29	18.69	21.23
Country	15.07	22.37	29.12
Region	42.60	49.28	55.84

Notes: Figures are expressed in percentage terms.

4.1 East Asia

Table 11 demonstrates variance decompositions for the East Asian countries. The country-specific factors capture the greatest share of output fluctuations in the region, explaining about 65 per cent of output volatility. However, the country-specific factors share of output volatility ranges widely across the East Asian region, from a low of 44 per cent in Japan to a high of 82 per cent in Korea and Thailand.

The world and region factors, on the other hand, play a relatively modest role in accounting for the economic activities in these countries. For the median country, only 8 per cent of the output variation is due to the world factor and only about 3 per cent of the output variation is due to the East Asian regional factor. The region factor is largest for the most developed economies in the region, namely, Japan, Korea and Singapore. The region factor accounts for about 7 per cent of output variation in these countries. In fact, the world factor share of output volatility also ranges widely across the region from a low of less than 1 per

²⁸ Figures for idiosyncratic factors are not reported here. Since there are only 28 countries in our model, the unexplained output movement (which falls under idiosyncratic factors) is expected to be large. Another explanation for the large role of the idiosyncratic factor is measurement error and this is especially true for developing or less developed economies.

cent in Indonesia to a high of more than 36 per cent in Japan. This result is consistent with that of Kose *et al.* (2003) who found Japan's world factor to be important.

4.2 Europe

Table 12 demonstrates variance decompositions for the European countries. The world factor explains more than 28 per cent of the output fluctuations in these economies. However, the world factor share of output fluctuations varies widely across these countries, ranging from a low of less than 2.5 per cent in Ireland and Norway to a high of 77 per cent in Belgium. Though less important than in East Asia, the country-specific factor explains a noticeable 23 per cent of output volatility in Europe. The country-specific factors, however, are more important for some countries in the region than others. For instance, country-specific factor account for more than 50 per cent of output volatility in Denmark and Norway and it accounts for more than 40 per cent of output volatility in Finland, France, Ireland and Spain. However, the country-specific factor only accounts for less than 5 per cent of output volatility in Belgium, Netherlands, Portugal, Sweden and Luxembourg.

The European regional factor, however, plays a relatively minor role in accounting for the economic activity in these countries: it accounts for about 5 per cent of output volatility in Austria and Luxembourg, and about 9 per cent of output volatility in Norway. The regional factors in the rest of the European countries are insignificant.

4.3 North America

Table 13 presents the variance decompositions for the North America. It is evident that the regional factor explains the majority of volatility in output, accounting for about 50 per cent of output volatility in US and Canada. The results for Mexico however, show a different trend with the country factor explaining the majority of the output fluctuation, the regional factor only explains less than 1 per cent of output fluctuation.

4.3 Summaries of Results

Our results here are not directly comparable with other studies except with that of Kose *et al.* (2003) who employ a similar model although they did not relate their results to the monetary union. Kose *et al.* (2003) also found that the size of the regional factor is more or less the same for EU and Asian countries. Similar findings, though based on other empirical models, have been made by a number of studies in the literature. Bayoumi and Eichengreen (1994), based on a decomposition of shocks between demand and supply shocks, find that there is little difference between Europe and Asia.

A few summaries can be drawn from the empirical findings of the symmetry of business cycle stems from the Bayesian State-Space Based approach. First, the country-specific factors capture the greatest share of output fluctuations in East Asia, explaining about 65 per cent of output volatility. It is a different phenomenon in EU and NAFTA with country factors explaining about 23 per cent of output fluctuations in EU and about 22 per cent in North America. However, the country-specific factors share of output volatility ranges widely across the East Asia region, from a low of 44 per cent in Japan to a high of about 80 per cent in Indonesia and Thailand. This difference can be explained by the difference in the degree of development in these countries. Kose *et al.* (2003) suggest that country specific factors tend to be more important for developing and poorer countries compared with the developed countries. Poorer countries tend to have more volatile business cycles that are country-specific.

Our results regarding the importance of the world factor being more important in explaining the business cycle fluctuations in the developed economies than those in the developing ones are also consistent with the findings in Kouparitsas (1997) and Kose *et al.* (2003).

Second, the region factors, on the other hand, play a relatively modest role in accounting for the economic activities in these countries. For the median country, only 3 per cent of the output variation is due to the East Asian regional factor. The region factor is largest for the most developed economies in the region, namely, Japan, Korea and Singapore. The region factor accounts for about 7 per cent of output variation in these countries. Our findings also indicate that regional factors play a minor role in explaining output variation in the EU economies as well. The regional factor seems to be playing its most important role in the North American region. This result is consistent with that of Kose *et al.* (2003).

Third, while the world factor explains a noticeable fraction of aggregate output volatility in the EU (more than 28 per cent) and NAFTA (more than 18 per cent) economies, it only explains 8 per cent of the output variation in East Asia. The world factor share of output volatility also ranges widely across the region from a low of less than 1 per cent in Indonesia to a high of more than 36 per cent in Japan. This result is consistent with that of Kose *et al.* (2003) who found that the world factor to be more important in explaining output fluctuations in developed countries while country specific factors are more important in developing countries.

5. CONCLUDING REMARKS

This paper examines the symmetry in business cycles of the East Asian as satisfying one of the preconditions for forming an OCA. We extend the existing literature by improving the methodology of assessing the symmetry shocks in evaluating the suitability of a common currency area in the East Asian economies employing the Bayesian State-Space Based approach. We consider a model of an economy in which the output is influenced by global, regional and country-specific shocks.

The empirical results suggest that the country-specific factors explain the majority of output volatility in the East Asian economies. Most of the East Asian economies exhibit little co-movement with the rest of the world compared with Europe and North America. The world factor explains a noticeable fraction of aggregate output volatility in the Europe and North American economies. Our findings also indicate that regional factors play a minor role in explaining output variation in both East Asia and the European economies. In economic discussions, the loss of the exchange rate instrument was often put forward as the main argument against monetary union. Although we do not find the evidence of a European cycle which provides a case for a regional common currency, the output in most European countries fluctuates due to shocks to the world economy. The regional factor seems to be playing its most important role in the North American region.

Our results imply that it could be costly to renounce individual currencies to advance into a currency union in East Asia as the output variations explained by country-specific factors is significant. For the time being, there may not exist scope for East Asia to form a monetary union for the time being. If a monetary union is a desired goal for the region, much work needs to be done to reduce disparities and to enhance policy coordination. The results of our study will only shed light on suitability of East Asia to form a single currency based on how far we are compared to the Euro Area in terms of the business cycle synchronization. Of course, many more studies that are outside the scope of this paper need to be done to examine the suitability of East Asia to form a single currency. Political will, for instance, is one of the key determinants of whether or not a country would join the monetary union.

Philippines	0.21	6.76×10^{-4}	8.85×10^{-4}	6.97×10^{-4}	4.20×10^{-4}
France	0.26	8.36×10^{-4}	1.59×10^{-3}	1.75×10^{-3}	1.76×10^{-3}
Austria	0.28	8.96×10^{-4}	8.88×10^{-4}	9.09×10^{-4}	7.82×10^{-4}
Belgium	0.19	6.14×10^{-4}	8.39×10^{-4}	8.95×10^{-4}	7.42×10^{-4}
Denmark	0.28	8.78×10^{-4}	7.47×10^{-4}	6.25×10^{-4}	4.27×10^{-4}
Finland	0.28	8.88×10^{-4}	8.40×10^{-4}	6.64×10^{-4}	5.65×10^{-4}
Germany	0.24	7.55×10^{-4}	9.92×10^{-4}	7.38×10^{-4}	4.46×10^{-4}
Greece	0.28	8.79×10^{-4}	1.01×10^{-3}	9.76×10^{-4}	7.95×10^{-4}
Ireland	0.31	9.65×10^{-4}	1.98×10^{-3}	1.61×10^{-3}	1.60×10^{-3}
Italy	0.30	9.47×10^{-4}	2.17×10^{-3}	1.72×10^{-3}	1.59×10^{-3}
Netherlands	0.30	9.38×10^{-4}	1.42×10^{-3}	1.37×10^{-3}	1.13×10^{-3}
Norway	0.28	8.72×10^{-4}	9.89×10^{-4}	8.75×10^{-4}	6.54×10^{-4}
Portugal	0.21	6.67×10^{-4}	1.40×10^{-3}	1.41×10^{-3}	9.97×10^{-4}
Spain	0.30	9.36×10^{-4}	8.21×10^{-4}	7.52×10^{-4}	5.31×10^{-4}
Sweden	0.28	8.89×10^{-4}	6.41×10^{-4}	5.82×10^{-4}	3.68×10^{-4}
Switzerland	0.29	9.14×10^{-4}	9.29×10^{-4}	9.45×10^{-4}	6.21×10^{-4}
UK	0.23	7.25×10^{-4}	1.51×10^{-3}	1.07×10^{-3}	7.96×10^{-4}
Luxembourg	0.31	9.71×10^{-4}	8.72×10^{-4}	7.32×10^{-4}	6.25×10^{-4}

Notes: NSE is calculated using the assumption of no serial correlation; $NSE1$ is calculated using the assumption of 4 per cent autocovariance taper;

$NSE2$ is calculated using the assumption of 8 per cent autocovariance taper and $NSE3$ is calculated using the assumption of 15 per cent autocovariance taper.

These tables present the results of posterior means, standard deviation and the $NSEs$ based on the assumptions of no serial correlation, 4 per cent autocovariance taper, 8 per cent autocovariance taper and 15 per cent autocovariance taper. For instance, the NSE relating to the estimation of $E(\beta_1 | y)$ is 4.80×10^{-4} , $E(\sigma_1^2 | y)$ is 8.09×10^{-8} and $E(\phi_1 | y)$ is 9.19×10^{-4} . The results indicate that we are achieving reasonably precise estimates.

Table 4: MCMC Diagnostics - Geweke's CD for β_i , σ_i^2 and ϕ_i

Country	β_i	σ_i^2	ϕ_i
US	1.49	-0.79	-0.57
Canada	1.87	-1.23	-1.47
Mexico	0.99	-0.22	-1.17
Singapore	1.09	0.55	1.09
Japan	1.49	-0.61	0.42
Korea	0.41	-1.21	-0.92
Malaysia	1.51	0.39	-1.90
Thailand	0.89	0.08	-1.53
China	0.83	-0.68	1.02
Indonesia	-1.20	-1.04	0.61
Philippines	-1.57	-0.86	0.52
France	0.94	-0.99	1.08
Austria	0.07	1.73	0.27
Belgium	-0.33	0.02	-0.32
Denmark	0.10	0.32	0.26
Finland	1.13	-0.68	0.52
Germany	1.93	-0.56	0.81
Greece	0.34	-0.45	-0.31
Ireland	1.47	-1.56	0.03
Italy	0.05	0.13	0.89
Netherlands	0.03	0.48	1.03
Norway	0.16	0.99	0.50
Portugal	0.69	1.92	-0.24
Spain	-0.48	-0.51	-0.03
Sweden	-0.13	-1.08	-0.61
Switzerland	-1.02	-0.89	0.17
UK	-0.83	-0.16	0.92
Luxembourg	-0.28	1.21	-0.52

Notes: Since CD is asymptotically standard Normal, a common rule is that if CD is less than 1.96 in absolute value for all parameters. We can conclude that convergence of the $MCMC$ algorithm has occurred.

Convergence Diagnostic (CD)

As pointed out by Koop (2003), the Gibbs sampler may yield misleading results if the initial replication is extremely far away from the region of the parameter space where most of the posterior probability lies. The *CD* will detect this problem as the draws are divided into 3 sets and the estimation based on the first half of the draws should be essentially the same as the estimate based on the last half. We follow the standard practice of setting $S_A = 0.1S_1$, $S_B = 0.5S_1$ and $S_C = 0.4S_1$. The reported results are based on $S_1=100,000$; therefore $S_A=10,000$, $S_B=50,000$ and $S_C=40,000$. Since *CD* is asymptotically standard Normal, a common rule is that if *CD* is less than 1.96 in absolute value for all parameters, we can conclude that convergence of the *MCMC* algorithm has occurred.

Table 4 shows the Geweke's *CD* for all the parameters β_i , σ_i^2 and ϕ_i . The figures shown in the table compares the estimation based on the first 10,000 replications (after the burn-in replications) to that based on the last 40,000 replications. It is evident that *CD* is less than 1.96 in absolute value for all parameters in Table 4. We can therefore conclude that the initial condition has vanished and an adequate number of draws have been taken. In other words, the *MCMC* algorithm has converged.

Highest Posterior Density Intervals (HPDI)

This section reports the posterior mean and the 95 per cent *HPDI* of β_i , σ_i^2 and ϕ_i in Table 5, 6 and 7 respectively. According to the reported figures in Table 5, 6 and 7, we are 95 per cent certain that all the parameters in the model (β_i , σ_i^2 and ϕ_i) lies within the *HPDI*. For instance, the mean for β_i is 0.31 which lies between the 95 per cent highest posterior density intervals of 0.074 and 0.58.

Table 5: MCMC Diagnostics - Posterior Mean and 95% HPDI for β_i

Country	Mean	95% HPDI	Pass (Yes/ No)
US	0.31	[0.074, 0.58]	Yes
Canada	0.20	[-0.028, 0.44]	Yes
Mexico	0.77	[-0.185, 1.76]	Yes
Singapore	0.41	[0.127, 0.70]	Yes
Japan	0.19	[-0.095, 0.48]	Yes
Korea	0.55	[-0.472, 1.61]	Yes
Malaysia	0.20	[-0.195, 0.60]	Yes
Thailand	0.42	[0.001, 0.84]	Yes
China	-0.01	[-1.249, 1.25]	Yes
Indonesia	0.97	[0.106, 1.82]	Yes
Philippines	0.66	[-0.518, 1.81]	Yes
France	1.34	[0.065, 2.57]	Yes
Austria	1.05	[0.654, 1.49]	Yes
Belgium	0.84	[0.445, 1.27]	Yes
Denmark	2.21	[1.436, 3.05]	Yes
Finland	0.30	[-0.183, 0.79]	Yes
Germany	0.45	[-0.064, 0.99]	Yes
Greece	0.60	[-0.777, 1.93]	Yes
Ireland	0.28	[-0.059, 0.63]	Yes
Italy	0.55	[-0.216, 1.31]	Yes
Netherlands	0.76	[-0.572, 2.07]	Yes
Norway	0.15	[-0.238, 0.54]	Yes
Portugal	0.14	[-0.315, 0.60]	Yes
Spain	0.47	[-0.903, 1.80]	Yes
Sweden	-0.74	[-1.327, -0.16]	Yes
Switzerland	-0.45	[-1.111, 0.21]	Yes
UK	-0.73	[-1.945, 0.50]	Yes
Luxembourg	-0.17	[-0.592, 0.24]	Yes

Notes: According to the reported figures above, we are 95 per cent certain that all the parameters in the model lies within the *HPDI*. For instance, the mean for US is 0.31 which lies between the 95 per cent highest posterior density intervals of 0.074 and 0.58.

Table 6: MCMC Diagnostics - Posterior Mean and 95% HPDI for σ_i^2

Country	Mean	95% HPDI	Pass (Yes/ No)
US	7.41×10^{-5}	$[4.25 \times 10^{-5}, 1.21 \times 10^{-4}]$	Yes
Canada	9.17×10^{-5}	$[5.09 \times 10^{-5}, 1.53 \times 10^{-4}]$	Yes
Mexico	3.84×10^{-4}	$[2.20 \times 10^{-4}, 6.12 \times 10^{-4}]$	Yes
Singapore	4.01×10^{-4}	$[1.36 \times 10^{-4}, 8.22 \times 10^{-4}]$	Yes
Japan	1.12×10^{-4}	$[5.68 \times 10^{-5}, 2.02 \times 10^{-4}]$	Yes
Korea	1.55×10^{-4}	$[7.90 \times 10^{-5}, 2.69 \times 10^{-4}]$	Yes
Malaysia	2.65×10^{-4}	$[1.26 \times 10^{-4}, 4.58 \times 10^{-4}]$	Yes
Thailand	2.13×10^{-4}	$[1.06 \times 10^{-4}, 3.76 \times 10^{-4}]$	Yes
China	3.17×10^{-4}	$[1.27 \times 10^{-4}, 6.03 \times 10^{-4}]$	Yes
Indonesia	2.56×10^{-4}	$[9.73 \times 10^{-5}, 5.27 \times 10^{-4}]$	Yes
Philippines	2.25×10^{-4}	$[9.25 \times 10^{-5}, 4.48 \times 10^{-4}]$	Yes
France	2.30×10^{-4}	$[1.32 \times 10^{-4}, 3.69 \times 10^{-4}]$	Yes
Austria	1.52×10^{-4}	$[9.19 \times 10^{-5}, 2.36 \times 10^{-4}]$	Yes
Belgium	9.77×10^{-5}	$[5.84 \times 10^{-5}, 1.53 \times 10^{-4}]$	Yes
Denmark	8.09×10^{-5}	$[4.73 \times 10^{-5}, 1.30 \times 10^{-4}]$	Yes
Finland	2.31×10^{-4}	$[1.32 \times 10^{-4}, 3.69 \times 10^{-4}]$	Yes
Germany	9.92×10^{-5}	$[5.97 \times 10^{-5}, 1.54 \times 10^{-4}]$	Yes
Greece	5.80×10^{-4}	$[3.63 \times 10^{-4}, 8.86 \times 10^{-4}]$	Yes
Ireland	4.26×10^{-4}	$[2.69 \times 10^{-4}, 6.44 \times 10^{-4}]$	Yes
Italy	1.48×10^{-4}	$[8.99 \times 10^{-5}, 2.29 \times 10^{-4}]$	Yes
Netherlands	1.08×10^{-4}	$[6.60 \times 10^{-5}, 1.68 \times 10^{-4}]$	Yes
Norway	1.48×10^{-4}	$[9.30 \times 10^{-5}, 2.26 \times 10^{-4}]$	Yes
Portugal	2.91×10^{-4}	$[1.54 \times 10^{-4}, 4.88 \times 10^{-4}]$	Yes
Spain	1.05×10^{-4}	$[6.50 \times 10^{-5}, 1.62 \times 10^{-4}]$	Yes
Sweden	2.57×10^{-4}	$[1.55 \times 10^{-4}, 3.97 \times 10^{-4}]$	Yes
Switzerland	2.93×10^{-4}	$[1.52 \times 10^{-4}, 4.81 \times 10^{-4}]$	Yes
UK	1.67×10^{-4}	$[1.01 \times 10^{-4}, 2.59 \times 10^{-4}]$	Yes
Luxembourg	9.15×10^{-4}	$[5.63 \times 10^{-4}, 1.41 \times 10^{-3}]$	Yes

Notes: According to the reported figures above, we are 95 per cent certain that all the parameters in the model lies within the HPDI.

Table 7: MCMC Diagnostics - Posterior Mean and 95% HPDI for ϕ_i

Country	Mean	95% HPDI	Pass (Yes/ No)
US	0.05	[-0.43, 0.52]	Yes
Canada	0.16	[-0.25, 0.57]	Yes
Mexico	-0.04	[-0.54, 0.47]	Yes
Singapore	0.13	[-0.34, 0.61]	Yes
Japan	0.24	[-0.24, 0.72]	Yes
Korea	-0.01	[-0.46, 0.45]	Yes
Malaysia	0.21	[-0.16, 0.57]	Yes
Thailand	0.09	[-0.38, 0.55]	Yes
China	0.18	[-0.23, 0.59]	Yes
Indonesia	0.05	[-0.44, 0.53]	Yes
Philippines	0.13	[-0.22, 0.48]	Yes
France	-0.01	[-0.45, 0.42]	Yes
Austria	0.15	[-0.32, 0.61]	Yes
Belgium	0.07	[-0.25, 0.39]	Yes
Denmark	0.12	[-0.34, 0.57]	Yes
Finland	0.05	[-0.41, 0.51]	Yes
Germany	0.10	[-0.29, 0.50]	Yes
Greece	0.09	[-0.38, 0.54]	Yes
Ireland	0.16	[-0.35, 0.65]	Yes
Italy	0.73	[0.19, 1.17]	Yes
Netherlands	-0.15	[-0.62, 0.35]	Yes
Norway	0.15	[-0.31, 0.60]	Yes
Portugal	-0.30	[-0.64, 0.05]	Yes
Spain	-0.04	[-0.53, 0.45]	Yes
Sweden	-0.01	[-0.47, 0.45]	Yes
Switzerland	0.00	[-0.47, 0.48]	Yes
UK	0.25	[-0.14, 0.61]	Yes
Luxembourg	-0.04	[-0.54, 0.47]	Yes

Notes: According to the reported figures above, we are 95 per cent certain that all the parameters in the model lies within the HPDI.

Table 8: Test for Heteroskedasticity

Country	<i>F</i> -statistics $F(4,23)$	Probability of <i>F</i>
US	0.42	0.80
Canada	0.61	0.66
Mexico	0.86	0.50
Singapore	1.68	0.19
Japan	1.29	0.30
Korea	0.14	0.97
Malaysia	2.68	0.06
Thailand	0.13	0.97
China	0.69	0.61
Indonesia	1.29	0.30
Philippines	0.65	0.64
France	1.46	0.25
Austria	1.07	0.40
Belgium	2.62	0.06
Denmark	0.49	0.74
Finland	1.46	0.25
Germany	0.93	0.46
Greece	1.63	0.20
Ireland	1.57	0.22
Italy	0.13	0.97
Netherlands	2.05	0.12
Norway	0.47	0.76
Portugal	0.33	0.72
Spain	1.45	0.25
Sweden	1.65	0.20
Switzerland	2.40	0.08
UK	1.26	0.32
Luxembourg	1.13	0.37

Notes: The critical value of 95th percentiles of the *F* Distribution for $F(4, 23)$ is 2.80. The *F*-Statistics for all countries are less than the critical value; therefore the null hypothesis of homoskedasticity cannot be rejected. The presence of heteroskedasticity is not detected in the model.
