ECONOMIC SIZE AND DEBT SUSTAINABILITY AGAINST PIKETTY'S "CAPITAL INEQUALITY"

Hye-jin Cho¹

¹Department of Economics, University of Paris 1, Pantheon-Sorbonne, PARIS, FRANCE

Abstract. *This article presents a methodology designed to facilitate alternative variables measuring economic growth. A capital-labor split of Cobb-Douglas function is adapted for use in the context of economic growth. A capital/income ratio and two fundamental laws of capitalism originated by Thomas Piketty illustrate capital inequality undervalued with respect to labor inequality. In addition, the article includes export and external debt as strong alternatives. Empirical data of the World Bank are analyzed to demonstrate broad differences in economic sizes. The case analysis on Latin America as an example of different sized economy is also discussed.*

Keywords: *capital-labor split, factors of production, capital/income ratio, Thomas Piketty, capitalism, economic size, debt sustainability, Latin America, import substitution industrialization (ISI) model, insolvent external debt, openness, external debt to exports ratio*

JEL Classifications: *E01; E22; G00; G01; H63*

Introduction

Questions about stability of the capital-labor split

“in the 2000s several official reports published by the Organization for Economic Cooperation and Development (OECD) and the International Monetary Fund (IMF) took note of the phenomenon (a sign that the question was being taken seriously). The novelty of this study is that it is to my knowledge *the first attempt to place the question of the capital-labor split and the recent increase of capital's share of national income* in a broader historical context by focusing on the evolution of the capital/income ratio from the eighteenth century until now. ”

Ref: Thomas Piketty (2014) Capital in the Twenty-First Century

Until when, can we use the Cobb-Douglas function with the mindset to believe the stability of the Capital-Labor split? A rational answer with alternative solutions should be pursued to this question. At the first step, we may comment on weakness of this method.

Firstly, the Solow residual which is a number describing empirical productivity growth in an economy from year to year and decade to decade is hard to be calculated because of it's "residual" which is the part of growth that cannot be explained through capital accumulation or the accumulation of other traditional factors, such as land or labor.

The equation in Cobb-Douglas form is: $Y=A K^{\alpha} L^{\beta}$ where total output Y is as a function of total-factor productivity A , Capital input K , Labor input L and two input's respective shares of output. (α and β are the capital input share of contribution for K and L respectively)

Even though Robert Solow defined rising productivity as rising output with constant capital and labor input perfectly, he left undefined part as the Solow residual. The problem is that Solow residual has pro-cyclicality. Traditionally, total output is measured by inputs of labor and capital. TFP (TFP) called multi-factor productivity (MFP) accounting for all inputs cannot be measured directly and accounts for effects in total output not caused by inputs. Indeed, there are two sided directions to analyze the economy.

Especially, Multifactor Productivity (MFP) is measured as below:

$$MFP_i = Y_i - \varphi_i \text{ where } Y_i \text{ denotes actual output and } \varphi_i \text{ denotes predicted output} \quad (1a)$$

$$\text{Log}_e(Y) = \alpha_0 + \beta_L \log_e(K_i) + \gamma_L \log_e(L_i) \quad (1b)$$

So we get, $MFP = \Delta(\ln f)/\Delta t = \Delta(\ln Y)/\Delta t - s_L \times \Delta(\ln L)/\Delta t - s_K \times \Delta(\ln K)/\Delta t$ where f is the global production function: Y is output, t is time, S_L is the share of input costs attributable to labor expenses, S_K is the share of input costs attributable to capital expenses, L is a dollar quantity of labor, K is a dollar quantity of capital, M is a dollar quantity of materials, S is a dollar quantity of (business) services, E is energy or exergy (available energy), only used in some models.

Secondly, like Total Factor Productivity (TFP), Growth accounting exercises are open to the Cambridge Critique. The aggregation problem is the major part of this debate. The style that the representative agent solves the decision problem in the function assuming the entire economy cannot be from the debate about the collection problem of different inputs, sudden shocks, rate of profit and a large number of heterogeneous workplaces. Hence, some economists believe that the method and its results are invalid.

Otherwise, we can indirectly establish the model to find determinants of TFP. Neoclassical economics started with the classical factors of production of land, labor and capital. Further distinctions from classical and neoclassical microeconomics include capital-the result of investment, fixed capital, working capital, financial capital and technological progress. Additionally, entrepreneurship, human capital, intellectual capital, social capital, natural resources and energy can be considered.

Table 1: Methodology about Factors of Production

Inputs: Three Factors of Production

Classical economics Adam Smith, David Ricardo: Labor, Capital Stock, Land (Natural Resource)

Marxism Labor, The subject of labor, The instruments of labor

Neoclassical microeconomics different format: Capital, Fixed Capital, Working Capital, Financial Capital, Technological progress

+add: Entrepreneurs (Frank Knight), Human Capital, Intellectual Capital, Social Capital (Pierre Bourdieu), Natural resources (Ayres-Warr), Energy

Output: Finished Goods (National Income)

Factor Payments: Rent, Wage, Interest, Profit

Ref: author, 2014

So we need to think "Weightiness" on Labor, Capital and other factors at the next step. I agree with the opinion of Thomas Piketty that structure of inequality with respect to both labor and capital has actually changed since the ninetieth century.

“To what extent are inequalities of income from labor moderate, reasonable, or even no longer an issue today? It is true that inequalities with respect to labor are always much smaller than inequalities with respect to capital. It would be quite wrong, however, to neglect them, first because income from labor generally accounts for two-thirds to three-quarters of national income, and second because there are quite substantial differences between countries in the distribution of income from labor, which suggests that public policies and national differences can have major consequences for these inequalities and for the living conditions of large numbers of people.”

Ref: Thomas Piketty (2014) Capital in the Twenty-First Century

Dynamics of the capital/income ratio of Thomas Piketty: $r > g$

“...If, moreover, the rate of return on capital remains significantly above the growth rate for an extended period of time (which is more likely when the growth rate is low, though not automatic), then the risk of divergence in the distribution of wealth is very high...”

“...This fundamental inequality, which I will write as $r > g$ (where r stands for the average annual rate of return on capital, including profits, dividends, interest, rents, and other income from capital, expressed as a percentage of its total value, and g stands for the rate of growth of the economy, that is, the annual increase in income or output), will play a crucial role in this book. In a sense, it sums up the overall logic of my conclusions.....”

Ref: Thomas Piketty (2014) Capital in the Twenty-First Century

Thomas Piketty put emphasis on capital inequality. This is the similar viewpoint of boom and bust. Boom and bust are periods of a severe business cycle over time. Several economic indicators are denoted as sustained increases followed by a sharp and rapid contraction. Times of increased business and investment have collapsed leaving widespread poverty such as the depression of 1837 and 1857 in the United States. For example, in the early 1800s in Ohio people were buying land on credit to sell at twice the price but land became too expensive to buy. At the same time, wheat prices became too low to transport wheat to market. Wheat was \$1.50 per bushel in 1816; by 1821, 20 cents. The automaker Paul Hoffman said "we cannot live with a crash with 26 depressions over 100 years including the burst of the 1930s."

The dynamics of the capital/income ratio adds a new perspective to the debate on capital and wealth. Previous study provides an overview of economic development. The direction of economic growth rate should increase to the top. However, the new viewpoint offers an alternative framework to demonstrate how the society actually moves. It examines different meanings of changes and directions with regard of economic growth. The attempt to be escaped by the required bilateral choice between capital and labor re-illuminates on alternative factors to research economic growth.

The First Fundamental Law of Capitalism $\alpha = r \times \beta$

With the aid of exploration of capital induced from national income, the first law of capitalism attempts to show visible motion of dynamics. It requires the fully-fledged account of global data because the formula produces the global interpretation without constraints. In the left side of formula, α can be added and in the right side of formula, $r \times \beta$ can be added. Hence, broader context with global empirical data is somewhat limited.

"In order to illustrate the difference between short-term and long-term movements of the capital/income ratio, it is useful to examine the annual changes observed in the wealthiest countries between 1970 and 2010, a period for which we have reliable and homogeneous data for a large number of countries. To begin, here is a look at the ratio of private capital to national income, whose evolution is shown in Figure 5.3 for the eight richest countries in the world, in order of decreasing GDP: the United States, Japan, Germany, France, Britain, Italy, Canada, and Australia." "Figure 5.3 (figure 1 in the paper as below) displays annual series and shows that the capital/income ratio in all countries *varied constantly in the very short run.*"

"... can now present the first fundamental law of capitalism, which links the capital stock to the flow of income from capital. *The capital/income ratio β is related in a simple way to the share of income from capital in national income, denoted α . The formula is $\alpha = r \times \beta$, where r is the rate of return on capital. ...*"

Ref: Thomas Piketty (2014) Capital in the Twenty-First Century

The first law of capitalism offers a subjective view of capital to focus on deviation of bilateral choice between capital and labor. Further evidence of the authenticity of the text is needed.

In the figure 1 (as below), the slope is upward in the end. It implies interpretation whether long-run or short-run economy is possible. However, depending on the date of the World Bank as below, it's impossible to explain about capital formation except for data of China. China has the highest gross capital formation (% of gross domestic production (GDP)) from 2004 to 2013. Indeed, this level is higher than the world's one. France, Germany, United States and Japan's graphs are similar except for China's one.

FIGURE 5.3. Private capital in rich countries, 1970-2010

Ref: piketty.pse.ens.fr/capital21c

Figure 1 : Private Capital in Rich Countries, 1970-2010

In the figure 2 (as below), gross capital formation (formerly gross domestic investment) consists of outlays on additions to the fixed assets of the economy plus net changes in the level of inventories. Fixed assets include land improvements (fences, ditches, drains, and so on); plant, machinery, and equipment purchases; and the construction of roads, railways, and the like, including schools, offices, hospitals, private residential dwellings, and commercial and industrial buildings. Inventories are stocks of goods held by firms to meet temporary or unexpected fluctuations in production or sales, and "work in progress." According to the 1993 SNA, net acquisitions of valuables are also considered capital formation.

Ref: World Bank national accounts data and OECD National Accounts data files, May, 2014

Figure 2 : Gross Capital Formation (% of gross domestic production (GDP))

The first law of capitalism gives fresh impetus to emphasize the role of capital to promote economic growth. It should be elaborated to describe the main features of dynamics related to global data for the possibility of wide cross-country comparison.

The Second Fundamental Law of Capitalism: $\beta = s / g$

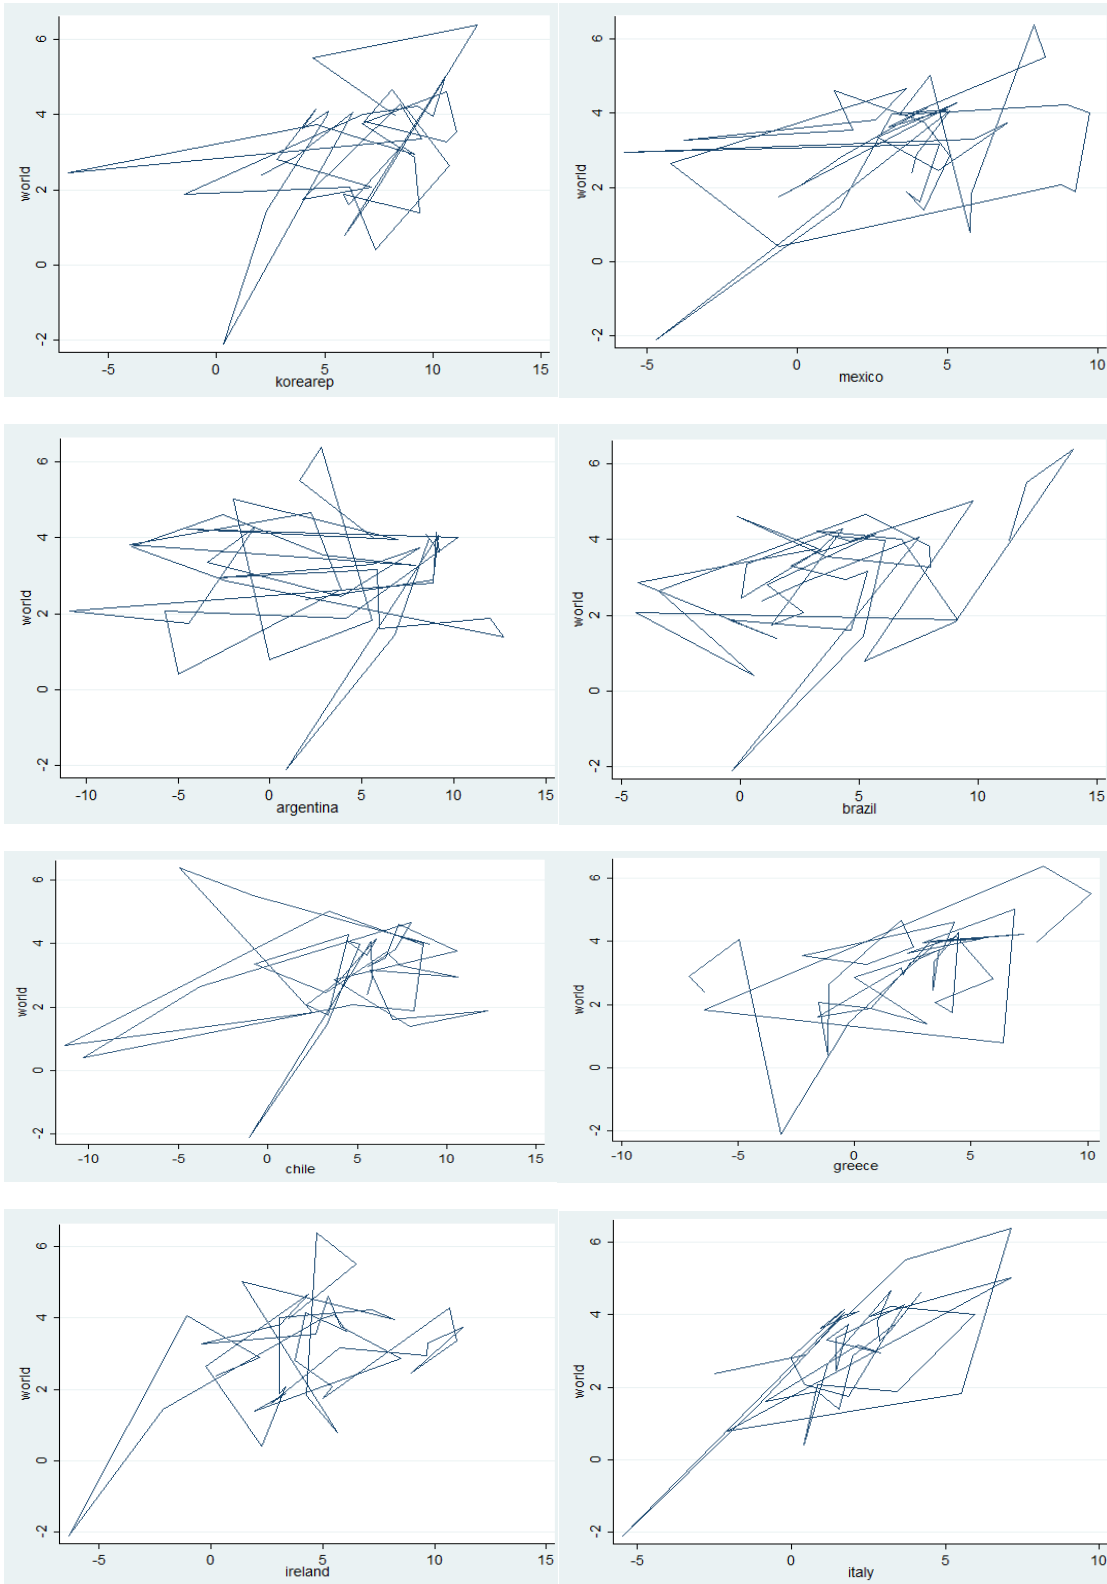

"...In the long run, the capital/income ratio β is related in a simple and transparent way to the savings rate s and the growth rate g according to the following formula: $\beta = s / g$"

Ref: Thomas Piketty (2014) Capital in the Twenty-First Century.

Gauging the general applicability related to the income rate to the growth rate is investigated by similarity between each gross domestic production (GDP) motion of different countries and world average motion.

As below, there are graphs of correlation between countries' gross domestic production (GDP) growths and the world's one. China has very different shapes of correlation with respect to the world's one from other's. This example is to test the hypothesis of the second law of capitalism. With the panoramic viewpoint of figure 3, the argument is evidently to make explicit cross-sectional data of different countries and thus contrast various interpretations upon which to different approaches to the contemporary management of past built environments are based.

Ref: author, 2014

Figure 3 : Graphs of Correlation between Countries' gross domestic production (GDP) Growths and the World's One

Gross domestic production (GDP) growth graphs of United Kingdom, United States, France, Germany, Japan, Ireland, Italy, Portugal and Spain have similar upward tendencies. China's one looks like South Korea, Mexico, Argentina, Brazil and Chile.

In addition, in the long run, can the capital/income ratio β be reflected by the volatility of the savings rate s and the growth rate g ? Within the context not to divide into countries depending on their economic sizes, then, we face aggregation problem. This brief empirical test here is intended to provoke the case that outstanding values than averaged value in the long run can exist. The second law of capitalism encapsulates the capital concern in general. However, it initiates a discussion of the stabilization of dynamics and boundary of optimal values by the end. Hence, in this paper, I will endeavor to explore new variables which can affect the left side and right side in the law of capitalism by absorption.

Economic Size and Debt Sustainability

Trade condition

Judging from stability of the capital-labor split, in the paper, attention was directed to weightiness of capital and labor. Two laws of Piketty's capitalism have centered on the capital inequality within national income. The main objective of arguments is to investigate the validity of global application because an idea of capital inequality takes economic growth as the focal point. In what follows, I explore key signifying variables. I hope to look most closely at familiar economic variables from a global angle.

I shall start by an attempt to check the correlation between average value of world and each value of each country with regard to exports of goods and services, gross domestic production (GDP) growth, GDP per capital, gross national income (GNI) per capital purchasing power parity (PPP), Gross capital formation, Gross savings, foreign direct investment (FDI) and inflation consumer price. What I propose to do here is to examine structural importance of key economic variables except for capital within world variables. I will use these empirical data as a framework against which to understand the capital within national income. I will concentrate on more rational way to address economic growth and capital inequality offering the global interpretation beyond the capital inequality framework within national income of Thomas Piketty.

Depend on data of World Bank, from 1970 to 2013, the correlation between world's one and countries' exports of goods and services is positive. (Observation 43)

Among the correlation with the world's one, exports of goods and services, GDP per capital and gross capital formation have positive correlation value. This is the reason why we need to focus on trade condition beyond no trade condition and complete market condition. The attempt to identify the law of capitalism by Thomas Piketty draws together the bulk of the published neoclassical papers mainstreamed by French Economists. I wish to flesh this out to take a highly microscopic approach to the question of economic growth. I begin with a case analysis of Latin America animated by a curiosity about impact of export and debt problematizing sovereign credit to affect the sustainability of each country and the whole economy in general.

To deal with the global framework of capital inequality and economic growth, I turn to state export and debt sustainability in a series of ratio analysis of Thomas Piketty. I may say that capital inequality within national income will be articulated with ideas about external debt to export. Having discussed empirical data, it is now time to focus on global activities beyond the domestic activities concerning sustainability of economic society.

Export and Debt sustainability

In case of debt sustainability, the debt to export criterion should be considered with the size of countries. (Roubini, N. 2001) Suppose you have two countries, A and B are identical. Their GDP is 100 each, their external debt is 50 each and their export is 20 each. Then the debt to GDP ratio is 50% for each and the debt to export ratio is 250% each. Assume that, at this ratio, both countries are solvent. Now take two countries and merge them. Total GDP will be 200, total debt will be 100 and total exports will be 20. Roubini, N. (2001) mentioned this is because exports among each other are now inter-regional rather than internationally tradable. At this point, the economic problem might be put with trade in a sense of the full context of framework considering the economic size.

By the end of this case, the combined A+B economy has a debt to GDP ratio that is still 50% but now the debt to export ratio is 500%, a figure concludes on a pessimistic note. In the light of the debt to export criterion, two economies are solvent if they are considered as two. On the contrary, they are insolvent if they are combined. This suggests that the debt to export ratio may be a faulty measure for solvency of larger countries; it suffices to say that “large” implies intra-regional rather than internationally tradable. Significantly, smaller countries with similar fundamental condition would look solvent just because their export to GDP ratio is higher than larger ones.

To put it more concretely, a small and opened economy, like Argentina, is usually more opener than a larger economy. It is lowly probable to say that the big economy, like Brazil, low export to GDP ratio undoubtedly reflect currency overvaluation, high degrees of trade protection and other policy restrictions to openness rather than the structure on the whole about lower openness. By the same token, the economy having a large debt to export ratio needs openness to service its external debt. For example, if export ratios are low, even a large real depreciation may not improve exports and trade balance enough to reduce a resource (trade balance) gap necessary to prevent insolvency so the degree of openness (export to GDP ratio) within countries or beyond countries does affect country’s ability to service its debt.

As below, through the dickey fuller test - examines whether a unit root is presented or not in an autoregressive model, validity of variables can be detected more. These data arranged yearly from 1970 to 2012 can be distinguished whether it has a unit root. The feature of processes can prevent serious statistical drawback at the beginning.

infconsumerp= inflation consumer prices, gsaving=gross savings, gcf=gross capital formation, gniperc=gni per capital ppp, gdpperc=gdp per capita, gdpg=gdp growth, exp=exports of goods and services

A clear understanding of empirical data about economic data requires reliability of raw data. In supporting the assumption that export and debt sustainability are keys to get to the heart of questions relating to the economic growth, I mentioned them with the empirical angle because it provides the necessary background for discussing capital to GDP and further GDP analysis related to capital inequality.

Debt management of Latin America

Debt-driven capital

In the 1960s and 1970s, Latin American countries, notably Brazil, Argentina, and Mexico, borrowed huge sums of money from international creditors for industrialization; especially infrastructure programs. After 1973, private banks had an influx of funds from oil-rich countries and believed that sovereign debt was a safe investment. Between 1975 and 1982, Latin American debt to commercial banks increased at a cumulative annual rate of 20.4 percent. This heightened borrowing led Latin America to quadruple its external debt from \$75 billion in 1975 to more than \$315 billion in 1983, or 50 percent of the region's gross domestic product (GDP). Debt service (interest payments and the repayment of principal) grew even faster, reaching \$66 billion in 1982, up from \$12 billion in 1975.

Failure of debt-driven capital

As interest rates increased in the United States of America and in Europe in 1979, debt payments also increased, making it harder for borrowing countries to pay back their debts. Deterioration in the exchange rate with the US dollar meant that Latin American governments ended up owing tremendous quantities of their national currencies, as well as losing purchasing power. The contraction of world trade in 1981 caused the prices of primary resources (Latin America's largest export) to fall.

Argentina has until midnight on July 30, 2014 to avoid going into default for eight times in its history. Most creditors exchanged their defaulted debt for new securities in two restructurings in 2005 and 2010 but a few creditors led by a hedge fund called NML Capital scooped up the cheap defaulted debt in order to chase payment of full principal plus interest. If Argentina defaults, its outstanding debt under foreign law amounts will be \$29 billion.

Why capital can not be simply explained within gross domestic production (GDP) : Attention to GDP replacing foreign imports – Import substitution industrialization (ISI)

Import substitution industrialization (ISI) is a trade and economic policy that advocates replacing foreign imports with domestic production. ISI policies were enacted by countries within the Global South with the intention of producing development and self-sufficiency through the creation of an internal market. ISI works by having the state leading economic development through nationalization, subsidization of vital industries (including agriculture, power generation, etc.), increased taxation, and highly protectionist trade policies. Import substitution industrialization was gradually abandoned by developing countries in the 1980s and 1990s due to structural indebtedness from ISI related policies on the insistence of the IMF and World Bank through their structural adjustment programs of market-driven liberalization aimed at the Global South.

ISI was most successful in countries with large populations and income levels which allowed for the consumption of locally produced products. Latin American countries such as Argentina, Brazil, Mexico, and (to a lesser extent) Chile, Uruguay and Venezuela, had the most success with ISI. This is so because while the investment to produce cheap consumer products may pay off in a small consumer market, the same cannot be said for capital intensive industries, such as automobiles and heavy machinery, which depend on larger consumer markets to survive. Thus, smaller and poorer countries, such as Ecuador, Honduras, and the Dominican Republic, could implement ISI only to a limited extent. Peru implemented ISI in 1961, and the policy lasted through to the end of the decade in some forms.

By the early 1960s, domestic industry supplied 95% of Mexico's and 98% of Brazil's consumer goods. Between 1950 and 1980, Latin America's industrial output went up six times, keeping well ahead of population growth. Infant mortality fell from 107 per 1,000 live births in 1960 to 69 per 1,000 in 1980 and life expectancy rose from 52 to 64 years. In the mid of 1950s, Latin America's economies were growing faster than those of the industrialized West.

More to the immediate point why the GDP is not just the GDP to consider the capital inequality: example of Export-oriented industrialization (EOI)

Export-oriented industrialization (EOI) sometimes called export substitution industrialization (ESI), export led industrialization (ELI) or export-led growth is a trade and economic policy aiming to speed up the industrialization process of a country by exporting goods for which the nation has a comparative advantage.

From the Great Depression to the years after World War II, under-developed and developing countries started to have the hard time economically. During this time, many foreign markets were closed and the danger of trading and shipping in war-time waters drove many of these countries to look for another solution to development. The initial solution to this dilemma was called import substitution industrialization.

Both Latin American and Asian countries used this strategy at first. However, during the 1950s and 1960s, Asian countries, like Taiwan and South Korea, started focusing their development outward, resulting in an export-led growth strategy. Most of Latin American countries continued with import substitution industrialization, just expanding their scopes. Some have pointed that out because of the success of Asian countries, especially Taiwan and South Korea.

Insolvent external debt of Latin America

Since the 1980 several countries in the region have experienced a surge in economic development and have initiated debt management programs in addition to debt relief and debt rescheduling programs agreed to by their international creditors. The following is a list of external debt for Latin America based on a 2012 report by The World Factbook.

Table 5 External Debt for Latin America

Rank	Country – Entity	External Debt (million US\$)	Date of information
26	Brazil	405,300	31 December 2012.
35	Argentina	130,200	31 December 2012.
40	Mexico	125,700	31 December 2012
45	Chile	102,100	31 December 2012.
49	Colombia	73,410	31 December 2012.
51	Venezuela	63,740	31 December 2012.
63	Peru	4,200	31 December 2012.
77	Cuba	22,160	31 December 2012.
78	Ecuador	20,030	31 December 2012.
81	Dominican Republic	16,580	31 December 2012.
82	Guatemala	16,170	31 December 2012.
83	Uruguay	15,900	31 December 2012.
85	Panama	14,200	31 December 2012.
86	El Salvador	12,840	31 December 2012.
88	Costa Rica	12,040	31 December 2012.
112	Nicaragua	5,228	31 December 2012.
114	Honduras	4,884	31 December 2012.
123	Bolivia	4,200	31 December 2012.
139	Paraguay	2,245	31 December 2012.

Openness and External debt to exports ratio

Debt burden indicators include the (a) Debt to gross domestic production (GDP) ratio, (b) External debt to exports ratio, (c) Government debt to current fiscal revenue ratio etc. This set of indicators also covers the structure of the outstanding debt including the (d) Share of foreign debt, (e) Short-term debt, and (f) Concessional debt in the total debt stock.

Table 6 : External Debt to Exports Ratio

Country - Entity (million\$)	external debt	exports	Ratio (External debt/Exports)
Brazil	405,300	242,000	1.674793388
Argentina	130,200	85,360	1.525304592
Mexico	125,700	370,900	0.338905365
Chile	102,100	83,660	1.220415969
Colombia	73,410	59,960	1.224316211
Venezuela	63,740	96,900	0.657791538
Peru	4,200	47,380	0.088644998
Cuba	22,160	5,600	3.957142857
Ecuador	20,030	23,770	0.842658814
Dominican Republic	16,580	9,467	1.751346784
Guatemala	16,170	9,864	1.639294404
Uruguay	15,900	9,812	1.620464737
Panama	14,200	17,970	0.790205899
El Salvador	12,840	5,804	2.212267402
Costa Rica	12,040	11,470	1.049694856
Nicaragua	5,228	4,160	1.256730769
Honduras	4,884	6,946	0.703138497
Bolivia	4,200	11,770	0.356839422
Paraguay	2,245	4,700	0.477659574

Ref: world fact book, 2012

The ratio of gross external debt to exports provides a quick indicator of the capability of an economy to repay external debt with enhanced revenue from sales to foreign countries. A ratio below 1 suggests that debt can be repaid rapidly, theoretically in less than one year. Conversely, the higher the ratio is the lower the country's capability to finance the debt with revenue from exports.

Having discussed the capital inequality issue, attention to the export variable and need of comprehensive ratio analysis: debt to export ratio and capital to income ratio, we will now proceed to investigate the risk management status of Latin America.

Risk management in major Latin America countries: (Mexico, Argentina, Brazil, Chile)

Among Latin America, the adoption of solvency II which is EU directive - codifies and harmonizes the EU insurance regulation primary concerning the amount of capital that EU insurance companies must hold to reduce the risk of insolvency- is realistic in Mexico. In the second half of 2008, the Mexican regulator (Comisión Nacional de Seguros y Fianzas, or CNSF) shared with the Mexican association of insurance companies (Asociación Mexicana de Instituciones de Seguros, or AMIS) a draft of a project of insurance law (the proposed law) in which a Solvency II-type regime was incorporated. The draft considered an initial date for this proposed law of January 2012. Since that time (end of 2008) through 2009 and the beginning of 2010, the proposed law was discussed and reviewed between CNSF and AMIS. The actual initial date is January 2014. However, the proposed law did not approved by the Mexican Congress.

If the strong solvency regulation is existed like Argentina, the conflict of two regulations between local solvency regulation and international one should be considered for the stable adoption. The current framework does not seem to indicate that an extended application of the Solvency II methodology will be feasible in the near future, except for offices and branches of European-based insurance companies.

The regulatory agency, SSN (Superintendencia de Seguros de la Nación) only mentioned the adoption of Solvency II without clear criteria. Actually, the insurance industry is tightly regulated in Argentina. SSN resolutions cover most aspects of insurance company activities, including unearned premiums and methods of mathematical reserve valuation. The agency establishes minimum valuation methods arising from formulas used to value out-of-court, mediation and lawsuit payables, as well as *incurred but not reported* (IBNR) claims reserves. Most insurance companies use these mechanisms to value their payables. As of 30 June 2011 (last fiscal year-end), all insurance companies in the market calculated their capital to be credited based on the issued premiums indicator. Of 155 insurers, only 4 carried minimum capital deficit as of this date. In recent months, the SSN announced the launch of a strategic plan of insurance, inviting all industry participants to bring their vision to define the insurance policy to be used during the period 2012–2020.

The existence of many solvency regulations can be analyzed with the conflict inside rules in Brazil so the Own Risk and Solvency Assessment (ORSA) is needed to integrate them. Brazil has adopted international regulations at each pillar. For Pillar I, the adoption of International Financial Reporting Standards (IFRS) as Brazilian generally accepted accounting principles (GAAP) in 2010. Detailed monthly reporting requirements of individual policy and claims data for the Insurance Supervisory Authority (Superintendência de Seguros Privados, SUSEP) were introduced in 2004 at the level of Pillar II. In 2004, the Supervisory Authority introduced the requirement that each insurance company should produce an annual actuarial valuation report proper to Pillar III.

In Chile, a new law that would require insurance companies to withhold risk-based capital was sent to Congress for approval on 30 September 2011. The methodology for calculating risk-based capital in Chile has yet to be made public. It is expected that the

Chilean regulator will publish a consultative white paper with details around the calculation of risk-based capital in the third quarter of 2012. The SVS (Superintendencia de Valores y Seguros) has demonstrated interest in performing the first Quantitative Impact Study (QIS) by the end of 2012.

Conclusion

A capital-labor split of Cobb-Douglas function which continues to be widely used by economists, has little empirical support. Even though neo-classical economists have proposed mathematical and theoretical realisms of economic growth by using the function, it was never empirically validated as the appropriate model for economic growth. Indeed, Thomas Piketty, a French economist, brought up this debated topic about capital inequality in his book, *Capital in the Twenty-First Century* in 2014.

I agree with him in that there is the structure of inequality with respect to both labor and capital actually changed since the ninetieth century of the chapter: Beyond Cobb-Douglas “The Question of the Stability of the Capital-Labor Split. Some research questions like “Did the Increase of inequality cause the financial crisis?”, “The illusion of marginal productivity”, “The Question of Time Preference” and “Is there an equilibrium distribution?” are fresh and fancy to break old fixed ideas.

I feel the solution is weak to support his brilliant idea enough. At the part4, the talk is suddenly changed to tax and pension (PAYGOs) without connection with previous capital inequality. Tax issues on Capital and Chinese millionaires are far from the real data of capital formation because it is very high value in China. We cannot see any empirical data of China’s one in his book even though the major capital part is by China. It seems hard to accept a solution of redistribution by immigration and an opinion about the central bank just as a loan deal before redistribution of wealth.

In the article, the most recent data shows that export and external debt may be correlated to explain economy growth. In the paper, Latin America history pervades the claim that capital within GDP of Thomas Piketty should be enhanced by conceptual capital related to debt and export beyond GDP. In addition, to point out miscalculation of ratio analysis depending on economic size, the example by Roubini, N. (2001) is demonstrated. To conclude, through the case analysis of Latin America, in detail, economic size and debt sustainability as economic growth indicators are emphasized by empirical data.

My sincere thanks go to Othmar M Lehner and the ACRN editorial team whose kind encouragement and willing assistance helped bring the article to a completed publication. My special thanks go to my supervisor Raphael Douady for selflessly encouraging my research and giving me fundamental support and my co-supervisor Duc Khuong Nguyen for quick and insightful guidance. Invaluable inspiration to figure out macroeconomic methodology on this article has been furnished by Axel Leijonhufvud, Daniel Heyman, Jesper Jespersen and all participants at seminars in 2014 by the university of Paris1 (Panthéon Sorbonne), the CEEL in Adaptive Economic Dynamics 2014 by the university of Trento, the 3rd Nordic Post-Keynesian conference by the Aalborg university. I wish also to record my appreciation to my family and JP.
