Broadband and Uneven Spatial Development: The Case of Cardiff City-Region

Jones, Calvin

Cardiff Business School

8 February 2018
Abstract

The internet and e-connectivity more generally are increasingly held to be an important element of business success. Evidence however suggests that the productive impacts of such technologies are contingent on factors that include firm size and sector, and human capital. It follows that if companies with these characteristics are unevenly distributed across space, the increasing importance of broadband in economic activity might impact unevenly on economic outcomes across space. We examine the Cardiff City-Region in South Wales, where the distribution of businesses and skills suggests that without policy intervention the roll out of broadband might further increase economic disparities between the relatively prosperous coastal belt and the poorer post-industrial hinterland.
1. Introduction

Technological change is progressing at an extremely fast pace. Information technology now allows production, sale and distribution and consumption to occur in ways unthinkable only a few decades ago (Kellerman, 2010). This fourth wave of the industrial revolution implies more fundamental changes in the way workers work and are managed, and in the scope of human work (Frey and Osborne 2017; Goldberg and Kehoe 2013). The first (English) industrial revolution, wherein a novel financial architecture combined with the exploitation of fossil fuels, had stark consequences for people and for places. The spatial distribution of people changed more quickly than any time in history (outside of wars and natural disasters), as new productive mechanisms required the clustering of workers in cities to be near factories (Floud et al, 2014). New industries and occupations were invented whilst some work became uneconomic; such urbanisation and sectoral change is a characteristic of economic development (Floud et al, 2014; Drakakis-Smith, 2012).

Current technological upheavals will have significant impacts on business location, place competitiveness and spatial development, especially as such developments enable automation and the wider application of artificial intelligence (Brynjolfsson, and McAfee, 2014). However, the spatial impacts of such developments have been understood rather broadly, if at all (Kerry and Danson, 2016). In the UK, government policy generally downplays the
importance of spatial elements in economic development and industrial and spatial planning interventions are limited (Bentley and Pugalis, 2013; Department for Business, Energy and Industrial Strategy, 2017). However, if industrial (and related social) change has uneven spatial impacts, there will be differential impacts on the economic success of diverse (Graham, 2002). For broadband particularly, whilst the roll-out narrative and associated debate is about connecting (and engaging) SMEs, and on the urban-rural divide, evidence suggests that impacts will be much more nuanced (Department for Culture, Media and Sport, 2015; Murray, 2016; Mack, 2015; Mack and Grubesic, 2009).

To investigate the potential for these spatially differential outcomes we examine the potential impact of high-speed broadband roll-out in the Cardiff Capital City-Region in Wales, a poor part of the UK. There are reasons why this is an illustrative case. Firstly, City-Regions and City-Deals are the primary way in which UK Government interacts with ‘economic space’; devolving relevant planning, development, transport and (sometimes) skills policies to city-region level political coalitions, along with budgets and challenging economic targets (O’Brien and Pike, 2015; HM Cabinet, 2016). Secondly, South Wales is an economically place. It currently has five levels of relevant governance – local authority; City-region, Welsh; UK and (historically developmentally-important) EU. It has a prosperity divergence between the coastal counties and the poorer post-industrial valleys, and a long history of policy intervention in innovation and ‘regional learning’ (Pugh 2014; Morgan, 2016).
This paper then presents an *ex ante* analysis of how broadband roll-out might impact economic development in different parts of the region, examining evidence from existing studies on what kinds of businesses and sectors benefit from e-connectivity and then suggesting which places across the Cardiff City-Region might win or lose (relatively) as the productive use of high speed e-connectivity becomes an increasing factor in economic success. The following Section briefly presents the policy context for the region and describes the scope and objectives of the 2016 Cardiff City-Deal. Section Three summarises what we know about how broadband (and ICT) contributes to productivity in businesses and hence to competitiveness. Sections Four and Five relate these findings to the business and workforce characteristics of the ten local authorities that comprise the City-Region; an analysis that strongly suggests that if internet-enabled activity is becoming more important, the net effect is likely greater spatial economic divergence. Section Six concludes.

2. City-Deals and City-Region Policy in the UK and Wales

After 2010 the UK Government made a strong statement on its approach to spatial economic policy, abolishing the nine English Regional Development Agencies in favour of smaller, business-led Local Enterprise Partnerships with a more limited remit and budgets. At the same time, planning and development policy in England was re-engineered (under Austerity) to become much more local, whilst innovation policy moved to the UK level (Pike *et al* 2016; Bentley
and Pugalis, 2010; Hildreth and Bailey, 2013; Kerry and Danson, 2016). Meanwhile, responsibility for development policy in general shifted, with the Department of Business Innovation and Skills (BIS) losing policy prominence and autonomy to the Treasury and Chancellor. This direction of travel continued under the 2015-17 Conservative Government with the Chancellor in *de facto* charge of spatial economic policy (in England). The only game in town – or at least English cities – was the devolution of development and related policy via bilateral agreements between the Treasury and city-region growth coalitions (O’Brien and Pike, 2013). A number of such agreements were signed offering policy devolution and a (sometimes modest) investment pot in exchange for attainment of ‘gateway’ targets, usually based on growth in Gross Value Added (GVA) or employment, and often on the promise to directly elect a local mayor (Meegan *et al.*, 2014). This City-deal approach was criticised as a way to shift perceived responsibility and accountability for the impacts of UK Austerity policies from Westminster to City Hall (Meegan *et al.*, 2014; O’Brien and Pike 2016). Despite the existence of devolved competence in relevant areas, eight Authorities in Central Scotland signed the Glasgow City Region City-Deal, with a £1.1bn investment fund, focussed on innovation and infrastructure hoping to create 28,000 jobs⁠¹.

---

More recently the Cardiff City Region City-Deal formally recognised the importance of devolved regional government by including the Welsh Government as a signatory (and source of funding) in a tripartite agreement\(^2\). The area in South East Wales covered by the Deal is in desperate need of regeneration. Whilst the five authorities that cover the coastal belt (two cities and two largely rural Counties, plus Bridgend) are relatively prosperous, the Valleys hinterland – home to around 1m people – suffers from long established economic and dysfunction related to the decline of coal mining and manufacturing (Dicks, 2014). Employment rates and economic inactivity in all Valleys authorities are worse than the UK (Jones et al, 2015). Whilst South East Wales overall has a GVA per head in 2014 at around 73% of the UK average, this ranges from around 90% of the UK in the NUTS3 area of Cardiff and the Vale of Glamorgan, down to only 65% of the UK in the Valleys (Office for National Statistics, 2017).

Cardiff has performed better economically than the rest of Wales, helped by employment growth over the longer term in (principally) retail and hospitality and the public sector. Of a total workforce in 2015 of 214,000, around 83,000 in-commute, 63,000 of these from Valleys authority of Rhondda-Cynon-Taff alone (Welsh Government, 2016). The long term shift of employment opportunities (along with population and infrastructure) from the Valleys to the coast, forms a

backdrop for city-regional policymaking, collaboration and debate. ‘Saving’ the Valleys has been a perennial theme, and with ameliorative policies over recent decades (whether enacted by UK government or Welsh Government) following the UK-standard approach developed in the 1980s. Inward investment, skills (and entrepreneurship) development, enterprise zones and new connectivity infrastructure are consistent themes (Dicks, 2014; Stroud et al, 2015); These interventions have failed to improve the position of the Valleys relative to the UK, for complex and poorly understood reasons (Foden et al, 2014).

3. Winners and Losers in the ICT and Broadband Revolution

The impact of information technology (ICT) on productivity has never been straightforward to conceptualise and measure, leading to Solow’s famous aphorism that ‘you can see the computer age everywhere except in the productivity statistics’ (see Triplett, 1999 for a discussion). This is in large part because it investments in ICT generate productivity increases over different (and extended) time periods, and require significant up-front investment, not just in terms of cash but also in complementary product and process innovation and in organisational restructuring (Brynjolfsson and Hitt, 2003; Pilat, 2005). ICT investment also has manifold potential impacts on firm productivity and hence competitiveness, with avenues including improved access to markets and suppliers; streamlined and lower cost management, logistical, design and other processes; and the spurring of within firm innovation (Bertschek et al, 2013; Higón, 2012). ICT also enhances of the productivity of some workers whilst
replacing others (Frey and Osborne, 2017; Levy and Murnane, 2012). Add to this uncertain time lags, the potential importance of unobserved variables and the relative weight of ICT impacts to other factors, and it is unsurprising that debate remains around just how (and how much) ICT affects productivity – or will in the future as ‘Industry 4.0’ advances become more embedded (Hempel, 2005; Brynjolfsson and McAfee, 2014).

This uncertainty is just as prevalent when assessing the firm-level (and consequent household and place) impacts of “broadband” adoption, with the question further complicated by a fast-moving technological environment. The term itself is easily understood as always-on, high-speed access to the internet, but the notion of ‘high-speed’ grew from 2 to 4Mbps in the US Federal Communications Commission definition of 2009, then to 25Mbps by 2015 (Federal Communications Commission, 2015). Then the question is not just whether (and how) broadband access might impact productivity, but also whether different available speeds (peak and/or average) or reliability might have different impacts – and indeed on different types of firms (Kenny and Kenny, 2011). Even when broadband access (or use) is treated as a binary, empirical difficulties remain, not least related to the lack of information available on how far firms have access to, and then use, broadband enabled services and then how these firms perform. Some country-level studies avoid such micro-empirical difficulties to suggest broadband roll-out spurs economic growth at national level, (Röller and Waverman (2001). Similar positive findings (again using a micro-macro approach) are reported by Koutroumpis (2009) for fifteen
EU countries between 2003-2006, and Katz et al (2010) suggest that for Germany the economic impact of broadband would total over €170bn by 2020. There is however a concern that in approaches shared by some macro-level studies (e.g. Czernich et al, 2011), instrumental variables often address broadband roll-out or availability not actual firm take-up, let alone productive use (Holt and Jamison, 2009; Forman et al, 2003).

Several studies have undertaken extensive survey work to fill the theoretical gaps. Grimes et al (2012) combined a (compulsory) survey of over 6,000 New Zealand businesses with a longitudinal business database to estimate a 7-10% productivity improvement consequent on broadband adoption. Such time- and firm-extensive data are the exception however. For example, while Bertschek et al (2013) surveyed 4,400 German businesses, their findings – that broadband positively impacted on innovation but not labour productivity – may have been affected by their two-year survey timeframe (2001-2003); perhaps too short to allow any innovative actions to play out. In Italy meanwhile, Colombo et al (2013) report on the (discoverable but very contingent) productivity impacts on Italian small and medium businesses whilst Haller and Lyons (2015) find no impact at all for Irish manufacturers. These firm level studies (and see Díaz-Chao et al, 2015; Hall et al, 2013) for work on ICT more generally) are complemented by a suite of ‘meso-level’ investigations that seek to examine the performance (or location) of firms in small areas (US Counties for example) that are differentiated by broadband provision or adoption (Mack, 2014; Whitacre et al, 2014; McCoy et al 2016). These investigations, mostly using US data, reveal
some interesting facts about the relative economic performance of places that benefit from broadband provision, and by implication the firms that are based there. This work is important in seeking to link broadband impacts with the local economic context (Kolko, 2012; Mack and Faggian, 2013; Mack and Rey, 2013). In each of these studies broadband is found to have economic and productive impacts (although not, perhaps for households), but only in partnership with other necessary within-firm, and perhaps place-related competencies and factors. Very recently a number of policy studies have emerged to suggest that the new technologies – automation, AI and the application of algorithms for example – that are e-connectivity enabled will have geographically differential impacts (for example Future Advocacy, 2017).

Drawing from this range of studies enables a picture of what types of firms, workers and places might benefit relatively more from broadband provision and/or take-up. Table 1 summarises these stylised facts, accepting the evidence is far from definitive. There are several factors that emerge with perhaps the clearest finding that for broadband to have positive economic impacts a high level of ‘complementary’ human capital is required – in terms of occupations and/or qualifications (Mack and Faggian, 2013; McCoy et al, 2016; Arvanitis and Loukis 2009). Another repeated finding is that ‘knowledge intense’ firms and specific industries – professional and business services, telecoms, utilities, finance and insurance – benefit more than manufacturing and retail operations (Kolko, 2012; Johnston et al, 2007; Mack 2015). The work of Elizabeth Mack and colleagues is especially interesting in a spatial context,
suggesting that not only the economic structure of a place matters, but also its relationship to other places – be this the relevant urban/metro core or dominant knowledge hub – as does economic history (Mack and Rey, 2013; Mack, 2015). Whilst some of these insights may directly apply only to the US context, the possibility that there is a nuanced relationship between broadband, business productivity and economic and geographic space is important when reflecting on a currently rather crude spatial context to broadband policy in the UK.

4. Cardiff Capital City-Region Case Study

The literature suggests that the productivity and growth impacts of broadband will be mediated by firms’ sector, orientation and size, and especially by the existence of complementary human capital. Because these factors are uneven over space – and because spatial factors themselves mediate broadband impacts – we can make an *a priori* judgement on how an economy which increasingly values the outputs of broadband-enabled activities, services and products will affect economic development over space. This is potentially applicable (and policy relevant) in a place such as the Cardiff City-Region, with significant differences in economic conditions, firm populations and skills and qualifications within a single functional economic area (Jones *et al*, 2015).

Wales is now at the forefront of Superfast (24Mbps+) broadband availability across most of its geography, largely due to a publicly funded roll-out of fibre (Ofcom, 2015), but as the literature makes clear the penetration or provision of broadband does not guarantee business take up, let alone productive use (Whitacre *et al*, 2014): this is by no means then wholly, or even largely, a ‘supply side’ problem (especially in Wales). If then, we assume that engaged
businesses who require broadband can access reliable and speedy services on site (or move premises), the question arises as to whether different parts of the city-region might, via their firms, workers and other economic characteristics, make ‘better’ use of this technology than others, with implications for within-region uneven spatial development (Boschma et al, 2013).

There are datasets that enable this forward-looking examination of potential spatial impacts. In most cases, relevant, up to date and reasonably robust economic data are available for the ten local authorities that comprise the Cardiff Capital city region, and this is how we structure our analysis\(^3\). These comprise the coastal cities of Cardiff and Newport, and largely rural coastal Counties of Monmouth and Vale of Glamorgan; plus five urban, post-industrial inland counties suffering severe economic and social deprivation (Rhondda-Cynon-Taff; Bleanau Gwent; Caerphilly; Merthyr Tydfil and Torfaen). The coastal County of Bridgend lies somewhere in between in terms of economic conditions and industrial history (see Map 1). At this spatial scale we can assess the skills and qualifications of the workforce; training levels; wages and the size and sector distribution of the private sector firm population. Key datasets include the UK Business Counts (Office for National Statistics, 2016a);

---

\(^3\) Some relevant data (for example on population skills and occupations) are available for 2011 from the UK Census at very local area and are the subject of a paper in development; see http://www.neighbourhood.statistics.gov.uk/dissemination/LeadHome.do.
As with extant US studies, the greatest lacuna relates to unobservable firm characteristics – including the composition of workforce, organisational approach and capability, and here access to (and take up of) broadband. There is also potential concern with our analysis: that of conflating issues relevant to the resident population of an area with those affecting local firms. In reality, many residents work in different counties, with Cardiff being by far the greatest attractor of labour; for Caerphilly and Vale of Glamorgan outflows of commuters are larger than the number of residents working domestically (Welsh Government, 2016). Here then we must be aware that there will be a complex relationship between broadband; firm productivity and success; local (within county) economic activity; and the welfare of the resident population. It may be
that (some) residents of a County are able to commute easily to work in innovative and productive broadband-enabled firms in more successful parts of the City-Region. We should not then conflate local economic activity with local welfare outcomes (see Section 6).

5. Data Presentation and Analysis

In this section, we draw from the factors presented in Table 1 to examine how well-placed firms and workers in the ten different counties that comprise the Cardiff City-Region may be to take productive advantage of broadband. We accept that these data are only indicative of actually-important firm and worker characteristics. Nonetheless, there are significant differences presented here that suggest the productive impacts of any (past or future) broadband roll out may be very unevenly spread. The post-industrial, inland part of the region (the five authorities collated in the tables as ‘Valleys’ (and highlighted in grey) share a number of important (negative) characteristics in comparison to the five (more heterogeneous) ‘Coast’ authorities. Unless otherwise noted, any differences between the Valleys and the Coast, are sufficiently large to be statistically significant at a 5% confidence level.

Table 2 presents some key summary data related to human capital across the City-Region, aggregated to Counties, using job-related training, qualifications and wages as proxies. It is notable that overall the poorer Valleys area performs
worse than the Coast in terms of resident human capital. The starkest difference is in the level of qualified population, where the five worst Counties are those in the Valleys (around 28% having a degree or equivalent), and where there is an over 11 percentage-point advantage for the Coast area (almost 40%). This difference is driven in part by the three higher educational establishments located (in whole or part) in Cardiff, but the two rural Coast counties have similarly high levels of qualified labour. Note we use the NVQ4+ level of qualifications here to address Mack and Faggian’s (2013) finding that it is this level of qualification that matters most for broadband impact, but Valleys authorities perform worse than the Coast at every level of qualifications attainment, albeit to a lesser extent (Office for National Statistics, 2016b). The position is somewhat better for the Valleys in terms of workers receiving job-related training in the prior 3 months, with two Valleys authorities in the ‘top five’ for training, although overall the level of job related training is lower in the Valleys.

It is worth noting that pay is much lower in the Valleys than on the Coast, suggesting lower levels of labour productivity and human capital embedded in Valleys workers and firms. Wages on the Coast are almost 8% higher⁴. Here there is some heterogeneity between Counties. Cardiff and Bridgend present

⁴ Here we have used estimates of the resident workforce from the Annual Population Survey (Office for National Statistics, 2106b) in conjunction with the Annual Survey of Earnings and Hours to estimate average gross wages for the Valleys and coast: there may then be some small error in our presented estimates for these aggregate areas due to differing survey methodologies.
the highest level of wages by far, related to in the first case, employment in high
value services and in the (relatively well paid) public sector, and in the latter
case many high-paying manufacturing jobs, including some large multinational
firms – although in Bridgend’s case, the susceptibility of well-paid but routine
manufacturing task to automation should be a concern (Frey and Osborne,
2017). Notably, the two Coast authorities that are in the lower half of the wage
distribution are the rural areas of the Vale and Monmouth, although sample
sizes restrict our ability to judge whether their rurality and consequent
agricultural and related employment are the cause. It is perhaps interesting that
there is some evidence that rural firms and areas benefit more from broadband
than others, but the notion of rurality and distance employed in the relevant US
studies is very different to that in the UK (Mack and Grubesic, 2009).

</tbody>
</table>
As far as the data allow us to judge then, the Valleys labour force would seem to be in a poorer position than that of the Coast to take productive advantage of broadband roll out. There is a caveat here however: so far, manual work that is harder to routinize and requires contextual awareness, such as driving, care work and food serving have resisted computerisation (as have high-end professional occupations), leading Goos and Manning (2007) to talk about the divergence of the economy into ‘lovely and lousy jobs’. The extent to which this remains true (witness for example very rapid recent strides in vehicle automation and the prevalence of order-via-screen in McDonald’s) will have important implications for areas that specialise in supplying labour for such dextrous occupations (Autor, 2015).

The results from prior studies also suggest that firms within the Valleys part of the region might less advantaged than those on the Coast by any increase in the economic importance in broadband-enabled activities (Table 3), although here data are more restricted and the findings from prior studies less definitive. In the first part of the Table, we follow Kolko (2012) and present information on the industries that appear to benefit most from broadband provision, amended from the US NAICS to UK-relevant SIC2007 categories\(^5\). The work of other studies such as Johnson et al, 2007 generally supports the finding that broadband and ICT has most impact in these industries.

\(^5\) 2-Digit SICs 36, 61, 62, 63, 64, 65, 66, 69, 70, 71, 72, 73, 74; covering utilities, telecoms, computing, financial services, professional and business services and technical and scientific activities
Here, again the data are clear. The first part Table 3 presents the percentage of firms located in each County and across our two sub-regions that are in Kolko’s top ‘broadband benefitting’ industries (industries that experience a 12%+ increase in employment following broadband penetration). The two Coast cities, and the two rural Coast counties have (proportionally) significantly more of such firms. The bottom five counties in this regard are our five Valleys authorities (Bridgend is closer to the Valleys than its Coast compatriots, but still marginally better; the dataset here, the UK Business Counts, is notionally at least a Census so sampling considerations do not apply). Overall the Valleys has 15% of its businesses in the most broadband-benefitting industries, the Coast 22.4%. The best authority in this regard, Cardiff, at 25.5% has almost 2.5 times (proportionately) more businesses than the worst (Blaenau Gwent at 10.5%).

The Table also provides information on the size of businesses in different counties, particularly in the medium-large size bands that studies such as Fornefeld et al 2008 and Johnston et al 2007 suggest might benefit more from broadband. Here we present the number of firms of such size in proportion to the resident population, as the overall number of firms (and hence local employment opportunity) varies across the region. We can see there is again a differential in favour of the Coast, with around 25% more such firms per head of population than the Valleys. Here, though, the rural Coast authorities perform quite poorly, with a relatively small ‘Mittelstand’ of mid-sized firms. Care needs to be taken here however with business size and broadband exploitation interacting in ways not fully understood (Fornefeld et al, 2008; Johnston et al,
2007), but the overall import of Table 3 is clear, reinforcing the earlier labour market analysis. If the existing US and EU evidence on the industrial impacts of broadband are correct, then poor Valleys authorities are likely to be less well positioned to benefit from broadband than the already relatively wealthy coast.

</table>

The analysis of US local areas and broadband productivity by Mack and Rey (2014), whilst only one study and in a very different national context, offers further concern. That paper suggests that the nature and hierarchy of metropolitan areas might affect how far broadband attracts ‘knowledge intense’ firms. Some findings may have limited application to the UK – for example that broadband may offset transaction costs in sprawling urban areas such as Las Vegas. However, the finding that broadband has less of an ‘attractive’ effect for metropolitan areas with an industrial past, and, a separate finding, for those in the rust belt states, may be important. Mack and Rey (2014) also suggest that new broadband provision in areas near already established technology or knowledge hubs has no economic impact. Our five Valleys authorities all have
an industrial legacy, and are all in the geographic shadow of Cardiff as the existing hub for knowledge intense firms. If broadband exploitation does rely in part upon the attraction of high value firms, the relative attractiveness of the Valleys and Coast should be considered relevant, especially given McCoy et al’s (2016) finding that in Ireland, broadband must be combined with high levels of local human capital to stimulate business re-location (as well as start-up).

In summary then, the evidence suggests that the prospect of broadband roll out narrowing intra-regional economic disparities in South Wales is remote, at least in the absence of ameliorative policy. The opposite is more likely, and indeed, the relative widening of intra-Wales economic disparities in the last decade may be in part related to telecommunications investments already enacted. If future competitiveness and productivity in ‘Industry 4.0’ relies increasingly upon leveraging cloud and internet infrastructures and services, and if ICT relatively enhances the productivity of the highest-qualified in the workforce who are concentrated on the Coast (and especially in the cities), then the ‘policy off’ prospect is for more uneven economic development within this (and perhaps other similar) regions (Graham, 2002; Akerman et al, 2015; Boschma et al, 2013).

6. Discussion

Much of the above analysis may come as no surprise to the authors of Cardiff’s original City-Region strategy (Welsh Government, 2012). This was predicated
on leveraging city-region development using Cardiff as the internationally recognised 'brand', and the key employment generator. Forecasts suggesting the population is to grow faster than any other UK city in the period to 2040 have reinforced this narrative (Welsh Government, 2013). This conceptual approach – effectively a Perrouxian growth pole paradigm emphasising agglomeration economies – is also inherent in the various city deals signed by the (former) UK Chancellor: Although the relevant deals are often light on detail the sense in reading the agreements is that cities, and their research and education establishments, hubs and brands, are the motive development force, and that the attraction of (inward) investment is the primary development mechanism. Under this reading of the economic landscape, cities will do their job of attracting investment and growing the employment base, providing economic opportunity for those living within the functional economic area. One can argue that the identification of the intra-region South Wales Metro transport network as the key project for the Cardiff City-Deal responds to the vision of Cardiff as offering increasing opportunity to better-connected Valleys residents.

However, as the literature shows, the ability of firms and places to benefit from broadband depends in large part on their available human capital (and the way it is organised). The penetration of ICT, the internet and cloud into businesses’ production functions will result in the increased value of some workers and occupations, and a fall in the productivity and usefulness of others. Individuals who live in poor places are more likely to be in the second category than those living in already prosperous, core locations, and we know the lower skilled and
qualified tend to search for employment more locally, and that spatial and social network factors matter in employment success (Cingano and Rosolia, 2012; Huber and Nowotny, 2013). The prospect then of Coastal-located broadband and cloud exploiting firms lifting all South Wales boats is remote.

There are some signs that the Welsh Government realises this danger; there has been a long debate about the structure and function of the South Wales Metro; the idea that it should enable polycentric development via the connecting of complementary regional ‘mini growth poles’ has come to the fore (Barry, 2016) and, the Welsh Government and the EU have sponsored a programme of business support to ensure SMEs in Wales are placed to take advantage of the benefits of Superfast Broadband. How far such regional policy actions can ameliorate pervasive economic disadvantages is of course an open question (McQuaid, 2002; Becker et al 2010).

6. Conclusions

There are ongoing and robust debates about the impact of technology on the demand for labour (Arntz et al 2016). Here, though we are less concerned with whether ICT and automation reduces demand for labour in aggregate, and more with whether it adds to or mitigates already-evident core periphery economic trends; this paper has sought to place the emergence of broadband-enabled firm activities and resultant economic development more firmly within a spatial context. Using the example of the Cardiff Capital City-Region in South
Wales, we can see that the increasing economic importance of e-connectivity would suggest (*ceteris paribus*) an increased level of economic disparity across space. This increased disparity would be driven by the very different levels of relevant human capital, and the very different industrial structures in the post-industrial Valleys and the more prosperous coastal cities and rural counties. Moreover, there is some suggestion in the literature that post-industrial areas, those near already established tech-heavy centres, will be less successful in attracting knowledge intensive firms (Mack and Rey, 2014)

This is not a happy analysis for those seeking more ‘even’ economic development. Technology-driven economic change may increase the unevenness of outcomes and – especially in large conurbations like the Valleys – creating geographically concentrated communities of lower skilled and poorly people for whom finding employment is increasingly difficult. The varied implications of these trends are important and worrying. Indeed, the increased importance of e-connectivity may already have contributed to the increased spatial economic divergence we have seen in the UK – North-South, intra-regional and intra-urban (Martin *et al*, 2015; Jones *et al*, 2015).

The current devolution of power to more local areas as part of the last and current UK Chancellors’ City-deal approach to economic development creates both threats and opportunities. The threat is in the implied and sometimes explicit orientation of the City-deals on global competitiveness, connectivity and
the identification of key city-regional industries and competencies as the path to
economic success. This approach may prejudice the success of poorer places
and people compared to the already relatively rich. The opportunity however
relates to the devolution of power to the lower spatial scale, where there may be
a more nuanced approach to economic development and a deeper
understanding of the challenges faced by both specific parts of society and
locales. Here, a more interventionist and ‘careful’ set of economic policies might
emerge which seek to harness the power of e-connectivity to build the
capacities of those currently economically left behind, and to spur a real ‘march
of the makers’ by renewing and re-equipping re-shored manufacturing to
succeed in the future economy (Bailey and de Propris, 2015). The ways in
which these tensions play out in city-regions, as their economies increasingly
automate, virtualise and head to the Cloud will be extremely interesting.
