Abstract

This paper studies the impact of the newly introduced science and technology innovation board (STIB) on stock valuations in China. This Nasdaq-style board features a market-based IPO system that contrasts with the current approved-based arrangement. Event study approach shows that A-share firms pertaining to STIB related industries increased significantly after the reform announcement. The effect is stronger for Non-SOEs and firms with higher R&D capacity. Public shareholders of the firms filing STIB IPO applications experienced salient growth in their abnormal returns while their industry competitors suffered price drops. Financial analysts also broadened their company coverages in STIB related industries and revised their market valuation forecasts positively in line with the market investors.

Keywords: China's financial reform, Registration-based IPO system, Science and technology innovation board in China, Chinese financial markets.*

JEL Classification Codes: G18, G38, N25, O16.

* The authors thank Xin Chen, Wenrui Liang, and Weijing Lin for their excellent research supports and delicate data collection efforts.

“The detailed rules for a Nasdaq-style start-up board in Shanghai have fueled hopes among early-stage companies the new regime could bring about positive changes in China’s stance towards raising equity that investors have been seeking..... If successful, the board could also position Shanghai as a capital-raising competitor to Hong Kong and New York, who between them accounted for 68.7 percent of the money raised through Chinese IPOs last year.....”

————— Reuters (February 11, 2019)

1. Introduction

China's economic reform over the last four decades has unleashed an unprecedented economic development. Meanwhile, its financial system demands a corresponding progress to support and promote the economic rise (Levine, 1999; Rousseau & Wachtel 2000; Beck & Levine, 2004). The Chinese stock market, whose total market capitalization ranked the second and the third in the world at the end of year 2017 and 2018 respectively, has witnessed a long-lasting prosperity ever since its establishment in 1991 (Franklin et al., 2018). Yet, the relatively lag of financial market accessibility contrasts with the rapid growth of its depth, as evidenced by the indices of financial market depth (FMD) and access (FMA) of China in Figure 1. Since the ability of firms to access financial market is pivotal in measuring one country’s financial system development and the prosperity of the economy (Levine, 2005; Svirydzenka, 2016), further reforms become urgent for both the short-run and long-run growth of Chinese economy. Chinese financial market accessibility, mainly featured by the initial public offering (IPO) system, however, is being widely challenged by its inefficient selection rules and process (Johanssona et al., 2017).

Under current practices, IPO applications need to respond to restricted and selected IPO qualifications, including profitability, cash flow, and asset quality, before formally approved by the Public Offering Review Committee of the Chinese Security Regulatory Commission (CSRC) (Chen & David, 2013; Song, Tan, & Yang, 2014)¹. Inefficient allocation during the IPO process is also detected and political connections are found to have a strong association with the approval and processing speed of initial public offering (IPO) activities in China (Li & Zhou, 2015). Joseph et al. (2014) and Tang et al. (2013) show that larger state-owned firms tend to have superior government connections and they are more likely to take advantages in IPO process. Thus, China's current IPO system calls for a transition from the approval-based arrangement toward a market-based mechanism (Cheng, Ouyang, & Tan, 2009; Cohn & Yinzhi, 2018).

Echoing such increasing demand, president Xi Jinping officially announced, on November 5, 2018, the establishment of the science and technology innovation board (STIB) that pilots the registration-based system during the First China International Import Expo. China Securities Regulatory Commission (CSRC) later officially issued the IPO guidelines for STIB in the evening of January 30, 2019 after the formal endorsement by the Central Comprehensively Deepening Reforms Commission, the

¹ According to CSRC current requirements, IPO companies should maintain their profits at an aggregate amount of more than RMB 30 million for the last three years; and their cumulative cash flows from operating activities for the last three years must exceed RMB 50 million or their cumulative operating income for the last three years must exceed RMB 300 million. For the requirements of asset quality, IPO company intangible assets (excluding land use rights, marine cultivation rights, and mining rights) can not surpass 20% of the net assets at the end of the latest year.

highest Chinese national policy maker. Besides the U.S. style registration system, the purpose of STIB, as claimed by the regulatory body, is to host companies in technology and emerging industries. Firms with growth potentials but experienced temporary financial losses are also eligible to be listed in the new board. CSRC is responsible for overseeing the filing firms and promoting full public disclosure and it will focus on the accuracy of information disclosure rather than firms' past performances. It is widely believed to be one of the most important financial reforms in Chinese market and the Shanghai and Shenzhen Composite rise about 5.23% and 9.90% in wake of CSRC announcement within the five trading days respectively.

In this paper, we shed light on shareholder valuations of this financial reform by analyzing the stock market reactions. According to the efficient-market hypothesis (EMH), stock markets respond instantly to policy shocks, as investors revise their beliefs momentarily. Thus, the prospects of the financial reform viewed by rational shareholders are indicated by the changes in stock valuations. The channels through which financial reform affects the cumulative average abnormal return (CAAR) are also examined by incorporating the potential heterogeneous impacts of the reform on different firms pertaining to various firm characteristics.

Our work finds that the CAAR of the STIB related industries increased significantly by 0.318% and 0.605% in one-day and three-day window respectively after the official IPO guidelines announcement, which shows an optimism for high-tech industry. Firm-level regression models further detect heterogeneous impacts of firms' characteristics

on the cumulative abnormal return (CAR). Non state-owned enterprises (Non-SOEs) and firms with higher R&D capacity also reacted positively in response to the reform announcement.

One typical concern of the event study approach employed above is that investors' over and under-reaction could be overlooked (De Bondt & Thaler, 1985; Hirshleifer & Subrahmanyam, 1998), even after the adjustment of size and beta (Chopra et al., 1992). These biases are also detected during the announcement of public policies (Bernanke & Kuttner, 1995). In emerging markets, Bailey et al. (2003) and Boubaker et al. (2015) find heterogeneous responses between analysts and stock market following a financial regulatory reform. By using analysts' forecasts, Sharpe (2002) examines the long-run valuations effect of inflation.

Thus, we, accordingly, substantiate our arguments by incorporating analysts' stock valuation based on the financial reform. Our results parallel the previous findings that Chinese analysts increased the P/E ratio forecast significantly for all of the companies in the market and for the companies that are categorized into the same industries which STIB targets after the guideline announcement.

Loosening the selection process is considered to be the most distinguished feature of the STIB, which creates more potential financing opportunities and hence improves firms' market value. We then directly investigate the investors' valuations of potential relaxations of firms' market financing accessibilities by focusing on the sample firms which have ownerships of the firms filing IPO applications. Many high-tech firms

rushed into filing applications to STIB after CSRC's announcement.² Using hand-collected data from their official prospects, ownership involvements by the A-share firms are detected. By adopting the event study approach again on individual filing date announced by the Shanghai Stock Exchange, we find significantly positive market responses in one-day and three-day event windows. Our result is also supported by empirical works that a positive valuation effect of parent firms exists when announcing carve-out decisions (Schipper & Smith 1986; Slovin et al., 1995; Allen, 1998; Hulbert et al., 2002). By employing firm characteristics, we demonstrate that the one-day and three-day CAR of Non-SOE companies were better than their SOE peers while listed companies with higher R&D expenditures growth rate in the past benefited more from the event.

Increasing competitions due to the financial reform could be the only “downside”, which harms the incumbents that directly compete with the firms that are eligible to be listed in the STIB. Existing literature finds that publicly traded industry competitors in the market experience negative stock returns in responses to their industry rivals' successful IPOs and positive stock price responses to their IPO withdrawal (Akhigbe, Johnston, & Madura, 2006; Hsu, Reed, & Rocholl 2010). Hulbert, Miles, and Woolridge (2002) echoes the evidences from competitors of carve-out parent firms by showing the negative announcement-period returns after the announcements of equity

² As of May 19, 2019, there are 109 companies submitting their application in STIB according to the WIND database.

carve-outs. Our results, consistent with previous studies, display a significantly negative stock return of the competitors listed in the main board after the announcement of IPO applications to STIB and the negative CAR was stronger for applicants issuing relative larger shares.

Our study relates to the existing literature in several folds. First of all, we are among the first studies targeting on the influences of registration-based system reform in financial market from emerging countries, while existing literatures mainly focused on financial regulatory policy changes and how it could promote market efficiency (Henry, 2002; Ángeles & Manzano, 2014; Huang, Li, & Chen, 2019). Our research develops current financial regulatory policy literatures by targeting on financial reform that systematically change from approved-based to registration-based system. We also deepen our study through how emerging financial markets would react to this significant financial shock, as well as how firm characteristics could affect the extent of this market reaction. Second, our study extends IPO literatures by considering the impact of announcement of potential IPO participants on financial market and how this financial reform could improve IPO efficiency while most of studies concentrated on IPO company characteristics, firm performance, as well as inefficient IPO policies (Ritter & Welch, 2002; Joseph et al., 2007; Tian, 2011; Song, Tan, & Yang, 2014). Third, our study supplements the existing research which mainly concerns how government subsidy program support high-tech company (Wallsten, 2000; DÉMURGER et al., 2002; Howell, 2017) since high-tech firms in many countries are

struggling with financial constrains for R&D and innovation (Hall, 2002; Himmelberg & Petersen, 1994; Bond, Harhoff, & Reenen, 2003). We, on the other hand, focus on how financial market was functioned by the government to financially support high tech companies.

2. Background and Significance of the Events

In order to improve its overall efficiency and allocation of capital of the market, the Chinese financial reform has been launched since the initiation of the security market in 1990. Tradition reforms for Chinese financial regulatory framework normally initiated from over-restrictive to over-unrestrictive, and then revised by supplementary regulations (Cheung, Ouyang, & Tan, 2009)³. The significant reforms in Chinese stock market history include: the launch of the restrictions of stock price in 1996; lessening stock brokerage fees in 2002; lessening the stamp duty in 2009; the split-share reform from 2005 to 2006; the initiation of margin trading and short selling in 2010, the introduction of stock index futures, government bond futures, and the ETF50 options in 2010; the start of the small-and-medium sized enterprises board in 2004, the growth enterprises market board in 2009, and the New Third Market in 2013; introduction of QFII in 2002, QDII in 2006, and RQFII in 2011; the establishment of the Shanghai-Hong Kong Connect in 2014, and Shenzhen-Hong Kong Connect in 2016. These

³ The over-restrictive regulations could generally screen ill-performed firms and thus protect investors. On the other hand, they also create high barriers preventing many small but promising companies from going public. At the same time, over-unrestrictive regulations, which allow more companies to enter into the capital markets, might also carry underqualified firms for investors (Cheung, Ouyang, & Tan, 2009).

reforms have made great contributions to the Chinese stock market. For example, the split-share reform in 2006 converted a large number of non-tradable shares to tradable shares in the market thus stimulating stock markets and promoting SOE firm performance (Li et al, 2011; Liao et al, 2014)

In spite of decades of financial reforms in China that have led the regulations more market-based, the selection procedure for IPOs is still more inclined to merits, which follows case-by-case evaluation systems being strictly supervised by the government (Johanssona et al., 2017; Li & Zhou, 2015). A further and deeper financial reform was considered to be necessary during the recent decades to further reduce financial frictions and constrains, to make a more financial liberalized and marketized Chinese security market, and to financially support national economy to grow healthily and solidly (Farrell, Lund, & Morin, 2006; Chan, Dang, & Yan, 2012; Peng, 2019; Sandra, Walter, & Vandenbussche, 2010). Moreover, the financial reforms are expected to channel more funds to private companies and small, medium companies, and high-tech initiatives, all of which has been regarded as the engine of growth in China's economy (Peng, 2019; Chen, Ke, Wu, & Yang, 2016). Such reforms with more financial opportunities would also be anticipated to provide Chinese savers substantially higher returns and thus elevate living standards and possibly consumption throughout the country (Chen & David, 2013).

These urgent requests stimulated a major financial reform of the Chinese capital market. Back to December, 2015, the Standing Committee of the National People's Congress

announced the authorization of the stock pilot registration system. The progress, however, grinded to a standstill in 2017. November 5, 2018, president Xi Jinping, officially announced the establishment of STIB and pilot registration system and depicted the promising development of this new-established financial market. And on January 30, 2019, the CSRC issued the guidelines of implementation of STIB and the pilot registration-based system in Shanghai Stock Exchange. According to the guidelines, STIB has no rigid requirements for the profits and capital structures of the IPO applicants, which fundamentally supports various technological innovations in the country⁴. STIB mainly targets on small and medium-sized technology start-ups and strategic emerging sectors with great growth potentials.

On March 1, 2019, the details of pilot registration-based System were released to further emphasize market information transparency and the roles of the CSRC, including the oversight on listed firms and possible illegal activities in the new board such as fraudulent IPO and false financial statement⁵. This registration-based system follows the US IPO mechanism that provides more flexibilities for stock issuance, trading, and

delisting, while releasing certain capital constraints of IPO companies (Barth & Jahera, 2010; Wright, 2002).⁶

3. Data, Sample, and Methodology

3.1 Event Study Methodology

Event study methodology is pervasive in assessing shareholders' valuation of some exogenous shocks based on efficient market hypothesis. Chinese market is functioning relatively efficiently since the prices of Chinese securities are strongly connected with listed firm fundamentals and the fluctuation of stock prices are as informative about future earnings as they are in the American market (Carpenter et al., 2018). Thus, Lin et al. (2018) analyzes the stock market response of China's anti-corruption movement while Fisman et al. (2014) estimates the abnormal return after the interstate frictions between China and Japan. Stock market reaction can also be gauged the potential impact of financial reforms. Schäfer et al. (2015) and Hackbarth et al. (2015) adopt the methods to assess the financial reforms relating the 1978 Bankruptcy Reform Act and the subprime crisis respectively. Following MacKinlay (1997), we utilize the single factor market model in the main analysis. The results are consistent if employing the

⁶ The financial accessibilities of high-tech enterprises grow with stronger market inclusiveness, and more diversified market functions (Brown, Fazzari, & Petersen, 2009; Padilla-Ospina et al., 2018). Information asymmetry in IPO is anticipated to be lessened by the involvement of the market investors and the influences of IPO companies and its CEO competencies (Gounopoulos et al., 2018).

Fama-French three-factor model (1993), following the spirit of Fisman et al., (2014) and Wang and Xu (2005).

In our event study, we use January 31 as T0 since the announcement of the financial reform is in the evening of January 30. The [-10, +10] days are selected as the event window to do our test. The estimation window is set to be [-180, -30] days.

3.2 Sample and Summary Statistics

The initial sample starts with public A share firms listed on the Shanghai and Shenzhen Stock Exchange. Financial, “special treatment” (“ST”), and National Equities Exchange and Quotations (NEEQ-listed) companies are excluded. All stock returns, ownerships, analyst forecasts, and the relevant financial data are extracted from the CSMAR database.

3.2.1 Measures on Firms’ Characteristics

Industries Related to STIB

To investigate the possible impacts of the reform on listed firms, various proxies on firms’ characteristics are examined through the event studies. First, we identify the listed firms who are classified to the same industries that are highly welcome to be listed in the STIB. According to the announcement issued by CSRC, the related high-tech industries were selected based on OECD industry classification, following the study from Galindo-Rueda and Verger (2016). These companies and their corresponding CSRC industry codes (2012) are presented in Table 1.

SOE and Non-SOE Firms

As non-state-owned firms (Non-SOEs) have relative disadvantages in accessing credit markets (Song et al., 2011), the financial reform that provides better environment for fund raising could relieve the credit constraint of Non-SOE firms more than that of the state-owned enterprises (SOEs). Therefore, we distinguish the SOE and Non-SOE firms by the code of equity nature provided by the CSMAR.

R&D

Eberhart, Maxwell, and Siddique (2004) identified that firms' shareholders would expect significantly positive abnormal return after the increase of R&D expenditures of their companies, while R&D intensity has also been considered as a major effect of firm performance (Lin, Lee, & Hung, 2006). Hence, we also study the influences of R&D growth rate and intensity (measured by R&D/Sales) towards CAR of the events.

Related Firms

Empirical work supports a positive valuation effect of parent firms when announcing carve-out decisions (Schipper & Smith, 1986; Slovin et al., 1995; Allen, 1998; Hulbert et al., 2002). To carry out the study of the abnormal returns of the listed firms that are shareholders of the potential IPO firms, we select related firms that are recorded by the WIND database. Besides, all financial data of the potential IPO firms are from the WIND database as well. The number of related firms is 53 (as of May 19, 2019) and their names and stock code are listed in Appendix I.

Competitor

As shown by Hsu et al., (2011) and Lee et al., (2011), the incumbents that directly compete with the potential IPO firms might be adversely affected. To quantify such impact, we manually collected the competitor information from the IPO prospects. Appendix II shows the IPO companies as well as their listed business competitors.

Analysts

As presented by Derrien and Kecskés (2013), analyst coverage on listed firms declines as a result of the real effects of financial shocks and the decline of analyst coverage would later aggregate information asymmetry and thus rises the cost of capital. Conrad et al., (2006) mentioned analysts are inclined to update their recommendation as large stock price increases or major news announced. Our research followed those research tracks and looked at the changes of analyst responses for the event, including analyst coverage and research report coverage. Analyst coverage is the number of analysts actively tracking and publishing opinions on firms within one year. Report coverage is the number of reports tracking and analyzing firms within one year.

The summary of the key variables of the study are shown in Table 2.

4. Empirical Framework and Results

4.1 The Market Reaction to the Policy Announcement

The event study methodology employed shows consistently and significantly positive stock market reactions for firms belonging to the related industries. Table 3 shows that

CAAR for three-day [0,3], five-day [0,5], and seven-day [0,7] is all significantly positive. Table??? demonstrates the trends of the CAAR through window [-10, 10] is moving upward around T0. The results accord with investors considering the event as important and good news to the market (Figure 2).

4.2 Firm-level Regressions of CAR for the Policy Announcement Date

Following Fisman et al., (2014), we incorporate the CAR generated from the event study to investigate the potential factors that affects the CAR. The regression model, which contains various firm characteristics, is stated as follows:

$$CAAR_i = \alpha + \beta_1 \text{firm characteristics}_i + \beta_2 \text{firm control}_i + \gamma_i + \epsilon_i \quad (1)$$

where $CAAR_i$ is the cumulative average abnormal return over the event window specified above. $\text{firm characteristics}_i$ includes the possible factors such as state-ownership dummy and R&D intensity and growth rate. Firm-level control variables are ROA, age, the logarithm of total assets, leverage ratio, and sales growth. We further control for industry fixed effects and the standard error is clustered at industry level. We first focus on firms pertaining to the industries that are highly likely to be listed in the STIB.

Table 4 shows that non SOE companies have a significantly higher CAR for both one-day [0,1] and three-day [0,3] event window, compared to SOE companies. The result reflects that non SOE could expect more benefits based on the signals of this new event, compared to the traditional advantages of SOE. The R&D intensity is also significantly positively related to CAR for both one-day [0,1] and three-day [0,3] event window,

while R&D growth rate is significantly positively related to CAR for one-day [0,1]. Also, the companies with higher R&D growth rate received more market investments after the events. The significant result of the interaction item, SOE* R&D growth rate, demonstrates that CAR of SOE company is less sensitive to its R&D growth rate.

In addition to the subsample analysis, we analyze the conceivable causes that affect firms that not only belongs to the aforementioned industry, as the financial reform could potentially benefits all firms listed in the exchanges by sending a positive signal to the whole market. Table 5 presents the significant results for the whole market, which echo to the outcomes from the related companies in the state-own natures, R&D growth rate, and interaction item SOE* R&D growth rate.

4.3 The Analysts Reactions to the Policy Announcement

Also, based on analyst forecasts, we compared P/E ratio for the industries that are highly likely to be listed in the STIB before and after event through the following regression framework:

$$P/E_i = \alpha + \beta_1 Post_i + \beta_2 firm\ control_i + \gamma_i + \epsilon_i \quad (2)$$

According to regression result as shown in Table 6, in the one-year forecasts, analysts revise a significantly higher P/E ratio for the related companies after the event. Later, an interaction item $Post_i * RD_Intensity_i$ was added to this regression and the significant result shows that the companies with high $RD_Intensity_i$ are inclined to have a higher predicted P/E ratio after the event. In addition, we extend the study to the whole industry to show how the entire market was viewed by the analysts. The result

from Table 7 echoes with the one with the related companies, P/E ratio for the whole market is significantly higher and the interaction item $Post_i * RD_Intensity_i$ is positively significant as well.

The analyst company coverage and report coverage for the related companies before and after the event are also studied:

$$Coverage_i = \alpha + \beta_1 Post_i + \beta_2 firm\ control_i + \gamma_i + \epsilon_i \quad (3)$$

As shown in Table 8, the results confirm with analysts' positive attitude toward market after the event and show that both analysts and their reports have a significantly higher coverage for the industries that are highly likely to be listed in the STIB.

4.4 The Related Parties' Reaction on the Prospectus Releasing Dates

We then investigate the investors' valuations of potential relaxations of firms' market financing accessibilities. To show the direct effects of relaxations of firms' market financing accessibilities, we look at the CAAR of the listed firms that have ownerships of firms filing IPO prospectus. According to the event study result, as shown in Table 9 and Figure 3, the event window [-3,3], [-1,1], [0,1], and [0,3] all present significantly positive responses. That implies stronger financing accessibilities for these shareholders in the market and justifies the positive vision of future market as the previous study indicated.

As for competitors of the listed firms (Competitor lists are shown in Appendix II) that have ownerships of firms filing IPO prospectus, they experienced a significantly

negative CAR in all of event windows (seen in Table 10 and Figure 4). These represent that these competitors are facing a worse financial situation in the market.

4.5 Firm-level Regressions of CAR for the Prospectus Releasing Dates

To specify the heterogenous impacts, the following familiar regression framework is proposed:

$$CAR_i = \alpha + \beta_1 R\&D\ growth_i + \beta_2 issue\ shares_i + \beta_3 firm\ control_i + \gamma_i + \epsilon_i \quad (3)$$

where i refers to those related firms which own shares of the STIB potential firms. $R\&D\ growth_i$ and $issue\ shares_i$ are the average R&D growth rate for the past three years and the listed companies' share proportions of the STIB companies, respectively. Similar firm-control variables and industry fixed effects are specified. The standard error is clustered at industry level.

The corresponding results are reported in Table 11 that both average R&D growth rate and the number of patents is positively correlated with the amount of CAR, which means the higher research expenditures and capacity, the higher market returns companies could generate. In this event. issue share percentages, on the other hand, present a negative correlation, which shows that higher issuing share percentages in STIB could dilute the ownership percentages of the shareholders.

The regression results for the significant firm characteristics that impact competitors CAR are shown in Table 12. It shows that issue share percentages are significantly negatively correlated with $CAR[-7,7]$, $CAR[-5,5]$, and $CAR[-3,3]$ of the competitors,

which implies that higher capitals that IPO applicants could raise, the lower market performance the competitors encountered.

5. Conclusion

This article investigates the Chinese stock market reactions to the establishment of the STIB with the pilot registration-based system. We find significantly positive abnormal returns following the policy announcement for related high-tech industries. Further regression models show that CAR is higher for non-SOEs and firms with higher R&D capacity in both the whole market and related high industry industries. The implication of these findings is that non-SOEs and firms with stronger technology and innovation could receive more recognitions from the market since the event. Besides, analyst attentions and valuations are also studied. The regression models show that analysts increase their valuations for the whole market and STIB related industries. Meanwhile, the number of the analysts covered these related industries increased. This result is in line with the previous market valuation findings. A variety of high-tech companies actively respond to the policy by submitting their applications. We then continue our investigations of the investors' valuations of potential relaxations of firms' market financing accessibilities by targeting on the sample firms with the shares of the firms filing IPO applications. Regarding the prospectus releasing day, public shareholders of the firms filing STIB IPO applications experienced positive cumulative abnormal returns while their competitors suffered from negative ones. These abnormal returns

are positively correlated with IPO applicants' R&D intensity and negatively related to the size of issue. This result shows that investors view the potential relaxations of firms' market financing accessibilities as a significant signal for the related parties.

As the research result shown, this significant financial reform stimulates the performance of the Chinese financial market and strengthen both investors' and analysts' confidences in the market and STIB related industries and companies. This will be a strong support for the Chinese financial system since the current approved-based IPO system is inefficient and incompatible with the China's gigantic stock market capitalization. The STIB is also aligned with national strategies in supporting high-tech industries with strong technology and innovation capacity, promising developmental prospects, and decent market recognitions. It will be a key ingredient of the "Made in China 2025" strategic plan. Meanwhile, the reform also shows a move made by the Chinese government to counter U.S. economic sanctions and restrictions on China's technology progression, including tightening rules around intellectual property theft and technology transfers. Thus, the development of STIB and future financial reforms is paramount importance for China's future economic growth. Our research provides confident evidences of the positive feedback from the market.

Table 1 Related High-tech industry distribution

CSRC Industry Code	Industry Name	Number of Firms	Percentage of Firms
I64	Internet and related services	42	4.93
C26	Manufacture of chemical raw materials and chemical products	178	20.89
C39	Manufacture of computers, communication and other electronic equipment	224	26.29
I65	Software and information technology services	74	8.69
C37	Manufacture of railway, ships, aerospace and other transportation equipment	39	4.58
M73	Research and experimental development	4	0.47
C27	Manufacture of medical products	164	19.25
C35	Manufacture of special purpose machinery	127	14.91
Total Number of Firms		852	100

^a The industry classification follows The Guidelines for the Industrial Classification of Listed Companies (Revised in 2012), issued by China Securities Regulatory Commission (CRSC)

^b According to the STIB announcement issued by CSRC, the related high-tech industries were selected based on OECD industry classification.

Table 2 Summary Statistic of main variables

SOE is an indicator variable that equal to 1 if the firm is State-owned enterprise, otherwise it is 0. RD intensity is measured as R&D expenditure divided by sales. RD Growth Rate is the average R&D expenditure growth rate. Sales Growth Rate is the average sales growth rate over most recently three years.

Variable	ALL firms						Related High-tech Industry					
	Total		SOE		Non-SOE		Total		SOE		Non-SOE	
	Mean	Std.	Mean	Std.	Mean	Std.	Mean	Std.	Mean	Std.	Mean	Std.
RD Intensity	0.01	0.08	0	0.02	0.01	0.1	0.01	0.04	0.01	0.04	0.01	0.04
RD Growth Rate	2.88	37.55	0.67	6.22	4.63	50.01	4.67	50.73	0.36	1.43	7.6	65.64
Sales Growth Rate	26.49	126.27	16.12	108.22	34.18	137.67	24.01	86.38	12.53	25.92	30.08	104.66
ROA	5.15	5.88	3.83	4.86	5.92	6.28	5.98	6.57	4.87	5.89	6.43	6.78
Age	20.75	5.58	22.46	5.01	19.76	5.66	19.97	5.54	22.02	5.14	19.13	5.48
Asset (billion yuan)	19.43	86.4	36.15	134.79	9.7	31.47	8.94	21.62	15.59	34.47	6.21	12.15
Leverage	0.43	0.2	0.49	0.2	0.39	0.19	0.37	0.18	0.43	0.19	0.35	0.17

Table 3 Cumulative average abnormal return for related high-tech industry firms

In this table, the cumulative average abnormal return (CAAR) of related high-tech industry firms around policy announcement date (31st January of 2019) are reported. Abnormal return is computed as the difference between the actual daily return and expected daily return over each indicated window. The expected return is estimated using market model by setting [-180, -30] trading days as the estimation window. Both T-statistic and Patell Z statistic and their corresponding P-value are reported.

Days	No. Firms	CAAR	T-Statistic	P-value	Patell Z-Statistic	Patel P-value
[-10,10]	812	0.46%	1.048	0.296	2.931	0.003
[-7,7]	812	0.83%	2.473	0.015	5.705	0.000
[-5,5]	811	0.63%	2.155	0.033	6.507	0.000
[-3,3]	812	0.18%	0.758	0.449	1.485	0.138
[-1,1]	812	0.22%	1.495	0.137	3.931	0.000
[0,1]	812	0.32%	2.586	0.011	5.750	0.000
[0,3]	812	0.60%	3.437	0.001	7.001	0.000
[0,5]	812	0.93%	4.282	0.000	9.223	0.000
[0,7]	812	1.20%	4.727	0.000	10.683	0.000
[0,10]	812	0.78%	2.582	0.011	8.908	0.000

Figure 2 Cumulative average abnormal return for related high-tech industry firm with event window of [-10,10]

The event date 0 is defined as the policy announcement date (31 January of 2019), Abnormal return is computed as the difference between the actual daily return and expected daily return over each indicated window. The expected return is estimated using market model by setting [-180, -30] trading days as the estimation window.

Table 4 Regression of firm characteristics on cumulative abnormal return around policy announcement date for related high-tech firms

This table presents the regression explains both 1-day [0,1] and 3-day [0,3] cumulative abnormal returns (CAR). Independent variables include the State-owned-enterprise indicator (SOE), R&D expenditure to sales (RD Intensity) and R&D expenditure growth rate (RD Growth Rate). Control variables are Average sales growth rate over most recently three years (Sales Growth Rate), Return on Assets (ROA), firm age (Age), firm size (log(assets)) and debt to assets (Leverage). All models include industry fixed effect and standard errors are clustered at industry level. t-statistics associated with coefficients are reported in parentheses, ***, ** and * indicate statistical significance at 1%, 5% and 10% levels, respectively.

Table 6 Analyst forecasting PE of 2018 revise due to policy announcement for related high-tech firms

This table presents estimates from a regression of related high-tech firm characteristics on analyst forecasting PE ratio for 2018, relative to industry fixed effects or analyst fixed effect. Independent variables include indicator variable (Post) which is defined as 1 if the forecasting is released after the policy announcement date of 31, January 2019, equals to 1 if the forecasting is issued before the date, R&D expenditure to sales (RD Intensity). Control variables are Average sales growth rate over most recently three years (Sales Growth Rate), Return on Assets (ROA), firm age (Age), firm size (log(assets)) and debt to assets (Leverage). t-statistics associated with coefficients are reported in parentheses, ***, ** and * indicate statistical significance at 1%, 5% and 10% levels, respectively.

Table 8 The change of analyst attention on related high-tech firm due to policy announcement

This table presents estimated analyst attention change due to policy announcement. Analyst attention is measured by analyst coverage and report coverage. Analyst coverage is the number of analysts actively tracking and publishing opinions on the firm within one year. Report coverage is the number of reports tracking and analyzing the firm within one year. Independent variable is the indicator variable (Post) which is defined as 1 for fiscal year 2017 and 0 for fiscal year 2018. Control variables include R&D expenditure to sales (RD Intensity), $\log(1+\text{Tobin's } Q)$, and debt to assets (Leverage). All models include industry fixed effect and standard errors are clustered at industry level. t-statistics associated with coefficients are reported in parentheses, ***, ** and * indicate statistical significance at 1%, 5% and 10% levels, respectively

VARIABLES	Analyst Coverage		Report Coverage

Table 9 Cumulative average abnormal return for ownership related listed firms

In this table, the cumulative average abnormal return (CAAR) of listed firms which are ownership related with STIB applicants announced prospectus releasing date are reported. Abnormal return is computed as the difference between the actual daily return and expected daily return over each indicated window. The expected return is estimated using market model by setting [-180, -60] trading days as the estimation window. Both T-statistic and Patell Z statistic and their corresponding P-value are reported.

Days	No. Firms	CAAR	T-Statistic	P-value	Patell Z-Statistic	Patel P-value
[-5,5]	51	1.84%	1.82	0.072	4.27	0.000
[-3,3]	50	3.90%	4.89	0.000	7.24	0.000
[-1,1]	51	4.72%	8.97	0.000	12.02	0.000

[-5,5]	51	1.84%	1.82	0.072	4.27	0.000

Figure 3 Cumulative average abnormal return for ownership related listed firm with event window of [-5,5]

The event date 0 is defined as the prospectus releasing date, Abnormal return is computed as the difference between the actual daily return and expected daily return over each indicated window. The expected return is estimated using market model by setting [-180, -60] trading days as the estimation window

Table 10 Cumulative average abnormal return for competitors

In this table, the cumulative average abnormal return (CAAR) of competitors to STIB applicants around prospectus releasing date are reported. Abnormal return is computed as the difference between the actual daily return and expected daily return over each indicated window. The expected return is estimated using market model by setting [-180, -60] trading days as the estimation window. Both T-statistic and Patell Z statistic and their corresponding P-value are reported.

Days	No. Firms	CAAR	T-Statistic	P-value	Patell	Patel
					Z-Statistic	P-value
[-7,7]	75	-2.92%	-2.60	0.011	-4.91	0.000
[-5,5]	75	-2.47%	-2.60	0.011	-4.82	0.000
[-3,3]	75	-1.71%	-2.26	0.026	-3.94	0.000

[-7,7]	75	-2.92%	-2.60	0.011	-4.91	0.000

Figure 4 Cumulative average abnormal return for competitors with event window of [-20,10]

The event date 0 is defined as the prospectus releasing date, Abnormal return is computed as the difference between the actual daily return and expected daily return over each indicated window. The expected return is estimated using market model by setting [-180,-60] trading days as the estimation window

Table 11 Regression of firm characteristics on cumulative abnormal return around prospectus releasing date for ownership related firms

This table presents the regression explains for 3-day [-1,1], 2-day [0,1] and 4-day [0,3] cumulative abnormal returns (CAR). Independent variables include R&D expenditure growth rate (RD growth rate), number of total patents (log (Patent), the percentage of newly issued shares (Issued share percentage). Control variables include firm size (log (Assets)), debt to assets (Leverage) and Average sales growth rate over most recently three years (Sales Growth Rate). All models include industry fixed effect and standard errors are clustered at industry level. t-statistics associated with coefficients are reported in parentheses, ***, ** and * indicate statistical significance at 1%, 5% and 10% levels, respectively.
