Abstract

This paper aims to investigate the nexus between domestic investment, exports, imports, and economic growth for the Brazilian economy during the period 1970-2017, using the VECM methodology. In the short-run, our empirical results pointed out that import, exports, and domestic investment cause economic growth. Also, economic growth causes exports. Exports, imports, and economic growth cause domestic investment. However, in the long-run, our results revealed that domestic investment and exports have a positive effect on economic growth. Also, imports have a negative effect on economic growth. The results recorded a positive impact of economic growth and imports on domestic investment. Exports have a negative effect on domestic investment. Finally, we record the absence of significant impact of economic growth, exports and domestic investment on imports, and economic growth, domestic investment, and imports on exports. Due to the importance of these aspects to the economic performance of Brazil, the policymakers are invited to orient these issues towards the sustainability facets to guarantee a sustained growth path.

Keywords: Export, Import, Domestic Investment, Economic Growth, VECM, Brazil.

JEL classification: E22, F14, O16, O47, O54.

1. Introduction

The growth of any economy strongly depends on the stock of domestic capital, which constitutes one of the main driving forces of the investment and value-added creation (See. [Tiba et al, 2015](#), [Bakari and Tiba, 2019](#); [Tiba and Frikha, 2019](#)). The neoclassical theory considered the capital accumulation process as the driving force behind a strong economic performance. Indeed, the accumulation of the capital is a fundamental element that will finance the investment, and then the economic growth will improve.

Also, the contribution of the movements of exports and imports are recognized in the creation of wealth and national prosperity due to the positive externalities obtained from the dynamism and interactions with the foreign actors under the globalization era.

Furthermore, the impact of the exports and imports on growth is structured around two hypotheses. The first hypothesis assumes that the export is the driving force of the economy that called the export leads-growth (ELG) hypothesis. Also, it supposes that the causality direction is running from exports to growth. While the alternative hypothesis assumes that the economic growth stimulates the export which is called the Growth lead-exports (GLE). The sense of causality is running from economic growth to exports.

Regarding the linkage between the imports and economic growth, where the imports lead-growth hypothesis assumes that the imports are the driving force of the economy (ILG). Moreover, the sense of causality is running from imports to economic growth. However, the alternative one assumes growth lead-imports (GLI), and the causality direction is from growth to imports. Due to the importance of domestic investment, exports, imports, and growth, the understanding of these controversial nexuses seen as a priority, especially, for the Brazilian case, where it is one of the most emerging economic power and member of the G20.

Our current survey attempts to treat the nexus between domestic investment, exports, imports, and growth for the Brazilian economy over the period 1970-2017. For this purpose, we employ the VECM methodology. To the best of our knowledge, none of the previous studies deal with this question in the Brazilian context through the use of the VECM technique.

The rest of the paper is structured as follow: Section 2 presents the empirical literature while Section 3 furnishes data and methodology. Empirical findings sited in Section 4. In the last section, we conclude the study and set up some policy suggestions for policymakers.

2. Literature Survey

The following Table presents a set of empirical studies that are collected during our exploitation of this research theme to inspire the realization of our empirical analysis.

Table 1 Studies related to the relationship between domestic investment, export, import and economic growth

Note: X means Exports, M means Imports, Y means Economic Growth, LR means Long Run, SR means Short Run, (+) means Positive Effect and (-) means Negative Effect.

3. Econometric methodology and data source

In this study, we use the following variables: economic growth (Y), domestic investment, (DI), exports (X) and Imports (M) for the case of Brazil. All the variables are taken from the online World Development Indicators data of the World Bank. Y is the variable referring to Gross Domestic Product (Constant US \$); DI is the variable referring to Gross Fixed Capital Formation (Constant US \$); X is the variable referring to total exports (Constant US \$); M is the variable referring to total imports (Constant US \$).

Following literature on economic growth {[Albiman and Suleiman \(2016\)](#); [Bakari \(2017\)](#); [Kartikasari \(2017\)](#); [Bakari \(2018\)](#); [Bakari and Ali \(2018\)](#); [Fakraoui and Bakari \(2019\)](#)}, we can consider the long-run and the short-run relationships between domestic investment, economic growth, exports and imports in linear logarithmic form.

$$\mathbf{Log(Y)}_t = \alpha_0 + \alpha_1 \mathbf{Log(DI)}_t + \alpha_2 \mathbf{Log(X)}_t + \alpha_3 \mathbf{Log(M)}_t + \varepsilon_t \quad (1)$$

The returns to scale are enclosed with domestic investment, exports and imports which are exposed by α_1 , α_2 and α_3 respectively. In addition, ε is error term and t is time index.

We use recent developments in time series econometrics to analyze the short-term and long-run causal relationships between domestic investment, exports, imports, and economic growth. This approach will be done in three steps: unit root tests, Johansen cointegration tests, Granger causality tests as part of an error-correction vector model.

3.1. Unit root tests

Unit root tests identify the presence of a unit root in a series. A time series is stationary if it has neither trend nor seasonality. The enhanced Dickey-Fuller test is used for this purpose. In this test, we try to verify the null hypothesis against the alternative hypothesis.

3.2. Cointegration Analysis

The study of cointegration makes it possible to test the existence of a stable long-term relationship between two non-stationary variables, including delayed variables and exogenous variables. The analysis of cointegration makes it possible to identify the true relationship between two variables, by looking for the existence of a cointegrating vector, and by eliminating its effect if necessary. Two series x and y are cointegrated if the following two

conditions are satisfied: they are assigned a stochastic trend of the same order of integration and a linear combination of these series leads to a series of the order of integration more lower. Finally, the Johansen cointegration test uses two statistics: the trace statistic and the maximum Eigenvalue. The asymptotic distributions of these statistics are nonstandard.

3.3.Vector Error Correction Model

The presence of a cointegration relationship between two variables leads to the existence of a causal relation between them in at least one direction. This causal relationship can be analyzed through the Granger causality test (Wald test), which relies on the Vector Error Correction Model. According to Granger's representation theorem, any cointegrated system implies the existence of an error-correcting mechanism that prevents variables from deviating too far from their long-run equilibrium. In addition, one of the important roles of Vector Error Correction Model is exterminating the causal relationship between all variables in the long run and in the short run.

To inspect the existence of a short-term relationship between variables, we will use the Wald Test. If the variable has a probability less than 5% in this case we can say that dependent variable cause independent variable in the short term. However, if the variable has a probability greater than 5% in this case, there is no causal relationship between variables in the short run.

To inspect whether there is a long-term equilibrium relationship in the estimation of vector error correction model (VECM), we use the method of Gauss-Newton linear regression. The coefficient of the Error Correction Term (ECT) must be negative and has a probability of less than 5%.

4. Empirical Results

Stationarity of each variable was checked through ADF with constant, constant and trend, without constant and without a trend. The below Table.2 examined the stationarity of each variable through ADF. The estimated results indicate that Y, DI, X, and M are stationary at first difference. The examined results confirm that Johansen Test can be applied with I (1) order.

Table.2 Test for Unit Test ADF

Variables	ADF Test		
	<i>Constant</i>	<i>Constant and Trend</i>	<i>None</i>

***; ** and * denote significances at 1%; 5% and 10% levels respectively
 () denotes stationarity in level
 [] denotes stationarity in first difference

Table.3 indicates the results of AIC, SC, and HQ with order test for lag selection based on VAR Model. According to the results of SC and HQ, lag zero is suitable (which is impossible), but AIC indicates that lag Seven is suitable for the model. We used AIC information criterion with indicate that lag seven is suitable for our model.

Table.3 VAR Lag Order Selection

VAR Lag Order Selection Criteria

* indicates lag order selected by the criterion
LR: sequential modified LR test statistic (each test at 5% level)
FPE: Final prediction error
AIC: Akaike information criterion
SC: Schwarz information criterion
HQ: Hannan-Quinn information criterion

The results of the Johansen co-integration test for series Y, DI, X, and M are reported in Table 3. The likelihood ratio tests show that the null hypothesis of absence of co-integrating relation ($R=0$) can be rejected at 5% level, but the null hypothesis of the existence of at most one co-integrating relation ($R<1$) cannot be rejected at the 5% level. This implies that in our case there are three co-integrating equation at the 5% level. Thus, we conclude that Y, DI, X, and

M are co-integrated. That is, there is a long-run relationship between economic growth, domestic investment, exports and imports for Brazil.

Table.4 Johansen co-integration test

Unrestricted Cointegration Rank Test (Trace)				
<i>Hypothesized No. of CE(s)</i>	<i>Eigenvalue</i>	<i>Trace Statistic</i>	<i>Critical Value 0.05</i>	<i>Prob.**</i>

At most 3	0.019852	0.782020	3.841466	0.3765

Trace test indicates 3 cointegrating eqn(s) at the 0.05 level
*** denotes rejection of the hypothesis at the 0.05 level**
****MacKinnon-Haug-Michelis (1999) p-values**

Since there are 3 cointegrating equations at the 5% level, Vector Error Correction Model can be returned. The estimation of the vector error correction model (VECM) has two steps. The first is to estimate the equation of long-run equilibrium by applying Gauss-Newton linear regression. The second step is to determine the causal links between the different variables in the short term by applying the WALD test.

The equations of the vector error correction model are presented as follows:

$$\begin{aligned}
 D(DLOG(Y))= & C(1)*(DLOG(Y(-1)) - 0.30743433369*DLOG(X(-1)) + 0.0921173554092*DLOG(M(-1)) - \\
 & 0.479377945542*DLOG(DI(-1)) - 0.00195092631235) + C(2)*D(DLOG(Y(-1))) + C(3)*D(DLOG(Y(-2))) + \\
 & C(4)*D(DLOG(Y(-3))) + C(5)*D(DLOG(Y(-4))) + C(6)*D(DLOG(Y(-5))) + C(7)*D(DLOG(Y(-6))) + \\

\end{aligned}$$

The equation of long-run equilibrium is presented as follows:

$$\text{Log}(Y) = 0.001951 + 0.479378 \text{Log}(\text{DI}) + 0.307434 \text{Log}(X) - 0.092117 \text{Log}(M) \tag{6}$$

Table 5: Estimation of VECM (Results of causality in Long run and short run)

	Log (Y)	Log (M)	Log (X)	Log (DI)
Log (Y)	-	(0.1840)	(0.0834)*	(0.0022)***
Log (M)	(0.0509)**	-	(0.5953)	(0.0124)**
Log (X)	(0.0018)***	(0.2769)	-	(0.0668)*
Log (DI)	(0.0160)**	(0.1217)	(0.4255)	-
ECT	[-7.553584]***	[-13.24822]	[-3.168606]	[-11.55755*]

***, ** and * indicate significance at 1%, 5% and 10%, respectively

() denotes the value of the probability of the variables in the short term

[] denotes the significance of long-term co-integration equations

The estimation of the vector error correction model shows the following results:

In the long run:

- ✓ Domestic investment and exports have a positive effect on economic growth.
- ✓ Imports have a negative effect on economic growth.
- ✓ Economic growth and imports have a positive effect on domestic investment.
- ✓ Exports have a negative effect on domestic investment.
- ✓ Economic growth, exports, and domestic investment don't have any effect on imports.
- ✓ Economic growth, domestic investment, and imports don't have any effect on exports.

In the short run

- ✓ Imports, exports, and domestic investment cause economic growth.
- ✓ Economic growths cause exports.
- ✓ Exports, imports, and economic growth cause domestic investment.

We have summarized these results in Graph 1 below:

Graph.1: The links between the four variables

To verify the credibility and the robustness of our error vector correction model, we apply a set of diagnostic tests. These are the heteroscedasticity tests and the residual autocorrelation test. The results of various diagnostic tests are given in the lower segment of Table 6. The diagnostic tests show that the estimation results are acceptable and that the model meets the MCO application conditions. Indeed, the probabilities of heteroscedasticity tests and the residual autocorrelation test are greater than 5%.

5. Conclusion

We attempt to treat the nexus between domestic investment, exports, imports, and economic growth for the emerging power of South America the Brazilian case over the period 1970-2017. In our framework, we use the VECM technique.

The short-run analysis pointed out that imports, exports, and domestic investment cause economic growth. The findings outline that economic growth cause exports. Finally, the highlights reveal that exports, imports, and economic growth cause domestic investment.

In the long-run, our results pointed out a positive influence of the domestic investment and exports on economic growth. However, the imports exert a negative impact on economic growth. Also, the short-run findings recorded that economic growth and imports have positive effect on domestic investment. Moreover, the results revealed a negative impact of exports on domestic investment in the Brazilian economy. However, economic growth, exports, and domestic investment have no significant impact on imports. Also, economic growth, domestic investment, and imports have no significant impact on exports.

From this outlook, our results pointed out the importance of exports, importance, and domestic investment to provide the phenomenal economic performance of the emerging economy such as Brazil as one of the G20 member States. Hence, the importance of the contribution of exports, imports, and domestic investment in economic growth following the neoclassical model. Besides, Brazil is invited to orient their exports, importance, and domestic investment towards sustainable goods and practices under the Sustainable Development Goals (SDGs) background of the United Nations.
