A Goodness-of-fit Test for Copulas

Artem Prokhorov*

August 13, 2008

Abstract

A new goodness-of-fit test of copulas is proposed. It is based on restrictions on certain elements of the information matrix and so relates to the [White (1982)] specification test. The test avoids the need to correctly specify and consistently estimate a parametric model for the marginal distributions. It does not involve kernel weighting and bandwidth selection or parametric bootstrap and is relatively simple compared to other available tests.

*Department of Economics, Concordia University, Montreal, PQ H3G1M8 Canada; email: artem.prokhorov@concordia.ca
1 Introduction

Copulas are useful because they allow to model dependence between random variables separately from their marginal distributions. Consider two continuous random variables $X_1$ and $X_2$ with cdf’s $F_1$ and $F_2$ and pdf’s $f_1$ and $f_2$, respectively. Suppose the joint cdf of $(X_1, X_2)$ is $H$ and the joint pdf is $h$. A copula is a function $C(u, v)$ such that $H = C(F_1, F_2)$ or, in densities, $h = c(F_1, F_2)f_1f_2$. The marginal densities $f_1$ and $f_2$ are now “extracted” from the joint density and the copula density $c$ captures the entire dependence between $X_1$ and $X_2$. Sklar (1959) showed that given $H$, $F_1$, $F_2$ there exists a unique $C$. So, given $F_1$ and $F_2$, the choice is which copula $C$ to use.

If the chosen copula is correct, $C(F_1, F_2)$ is the correct joint distribution of $(X_1, X_2)$. Then one may base an estimation of the dependence parameters (parameters of the copula function) on the correctly specified joint likelihood without worrying about modeling the marginal distributions (they can be estimated nonparametrically). Such likelihood-based estimators are consistent. They have been used extensively in applications in finance (e.g., Patton, 2006; Breymann et al., 2003), in risk management (e.g., Embrechts et al. 2003, 2002) and in health and labor economics (Smith, 2003; Cameron et al., 2004).

However, if the copula function is incorrect, the joint distribution is misspecified. This generally means that estimators based on the joint likelihood will be inconsistent. In particular, the copula dependence parameter will be inconsistent whether the marginal distributions are estimated parametrically or nonparametrically. Moreover, copula misspecification may affect consistency of marginal parameter estimates. Suppose interest is in efficient estimation of the marginal distribution parameters using copula-based likelihood. Under copula misspecification, such estimators are generally inconsistent (see Prokhorov and Schmidt, 2008).

It is therefore important to have a simple and reliable test of copula correctness.

There exist several copula goodness-of-fit tests. Panchenko (2005) proposes a test based on a V-statistic. His test has an unknown asymptotic distribution and depends on the choice of bandwidth. Nikoloulopoulos and Karlis (2008) propose a test based on the Mahalanobis squared distance between the original and the simulated likelihoods. Their test uses parametric bootstrap. Fermanian (2005) proposes two tests based on a kernel estimation of the copula function. Dobric and Schmid (2007) propose a test based on Rosenblatt’s transform. Their test procedure is not directly applicable if the marginal distributions are unknown. Prokhorov and Schmidt (2008) propose a conditional moment test, which tests if the copula-based score function has zero mean. Their test does not distinguish between the correct copula and any
other copula that has a zero mean score function.

The test proposed in this paper is based on the information matrix equality which involves the copula-based Hessian and outer-product of the score. The statistic has a standard distribution and accounts for the use of empirical marginal distributions in place of the true ones. The test is proposed in Section 3. Section 2 discusses the connection between copulas and the information matrix equality. As an illustration, Section 4 tests goodness-of-fit of the Gaussian copula in a model with two stock indices.

2 Copulas and Information Matrix Equivalence

Consider an $N$-dimensional copula $C(u_1, \ldots, u_n)$ and $N$ univariate marginals $F_n(x_n)$, $n = 1, \ldots, N$. Then, by Sklar’s theorem, the joint distribution of $(X_1, \ldots, X_N)$ is given by

$$H(x_1, \ldots, x_N) = C(F_1(x_1), \ldots, F_N(x_N)). \quad (1)$$

Assume $F_n$ are continuous, so $C(u_1, \ldots, u_n)$ is unique.

The joint density of $(X_1, \ldots, X_N)$ is

$$h(x_1, \ldots, x_N) = \frac{\partial^N C(u_1, \ldots, u_N)}{\partial u_1 \cdots \partial u_N} \bigg|_{u_n = F_n(x_n), n = 1, \ldots, N} \prod_{n=1}^N f_n(x_n) \quad (2)$$

$$= c(F_1(x_1), \ldots, F_N(x_N)) \prod_{n=1}^N f_n(x_n),$$

where $c(u_1, \ldots, u_N)$ is the copula density.

Copula functions usually include parameters. For example, the $N$-variate Gaussian copula includes $N(N - 1)/2$ parameters. This copula has the form

$$\Phi_N(\Phi^{-1}(u_1), \ldots, \Phi^{-1}(u_N)), \quad (3)$$

where $\Phi_N$ is the joint distribution function of $N$ standard normal covariates with a given correlation matrix and $\Phi^{-1}$ is the inverse of the standard normal cdf. For the Gaussian copula, the copula parameters are simply the distinct elements of the correlation matrix used to construct the multivariate normal distribution $\Phi_N$. (See Nelsen 2006, Joe 1997, for other examples).
Let subscript $\theta$ denote the dependence parameter vector of a copula function and let $p$ denote its dimension. It is well known that if there exists a value $\theta_0$ such that $H(x_1, \ldots, x_N) = C_{\theta_0}(F_1(x_1), \ldots, F_N(x))$ then we have a correctly specified likelihood model and, under regularity conditions, the MLE is consistent for $\theta_0$. Moreover, in this case White (1982)’s information matrix equivalence theorem holds: the Fisher information matrix can be equivalently calculated as minus the expected Hessian or as the expected outer product of the score function.

More notation is needed. Assume that the likelihood is (three times) continuously differentiable and the relevant expectations exist. Let $H_\theta$ denote the expected Hessian matrix of $\ln c_\theta$ and let $C_\theta$ denote the expected outer product of the corresponding score function. Then,

$$H_\theta = E\nabla^2_\theta \ln c_\theta(F_1(x_1), \ldots, F_N(x_N))$$

$$C_\theta = E \nabla_\theta \ln c_\theta(F_1(x_1), \ldots, F_N(x_N)) \nabla'_\theta \ln c_\theta(F_1(x_1), \ldots, F_N(x_N)),$$

where “$\nabla$” denotes partial derivative with respect to $\theta$.

The White (1982) information matrix equivalence theorem essentially says that, under correct specification of the copula,

$$-H_{\theta_0} = C_{\theta_0}. \tag{4}$$

The copula mis specification test we propose uses this equality.

3 Testing Procedure

In practice we do not observe $\theta_0$. Moreover the matrices $H_\theta$ and $C_\theta$ contain the marginals $F_n$ which are often unknown. We can, however, easily estimate these quantities. In particular, it is common to use the empirical distribution function $\hat{F}_n$ in place of $F_n$, a consistent estimate $\hat{\theta}$ in place of $\theta_0$, the sample averages $\hat{H}$ and $\hat{C}$ in place of the expectations $H$ and $C$.

Given $T$ observations on $(x_1, \ldots, x_N)$, the empirical distribution function is given by

$$\hat{F}_n(s) = T^{-1} \sum_{t=1}^{T} I\{x_{nt} \leq s\}, \tag{5}$$

where $I\{\cdot\}$ is the indicator function and $s$ takes values in the observed set of $x_n$. Then, $\hat{\theta}$ – a consistent estimator of $\theta_0$ sometimes called the Canonical Maximum Likelihood estimator – is the solution to

$$\max \sum_{t=1}^{T} \ln c_\theta(\hat{F}_1(x_{1t}), \ldots, \hat{F}_N(x_{Nt})).$$
To introduce the sample versions of $H$ and $C$, we define new notation. Let

\[
H_t(\theta) = \nabla^2 \ln c_\theta(\hat{F}_1(x_{1t}), \ldots, \hat{F}_N(x_{Nt})), \\
C_t(\theta) = \nabla_\theta \ln c_\theta(\hat{F}_1(x_{1t}), \ldots, \hat{F}_N(x_{Nt})) \nabla'_\theta \ln c_\theta(\hat{F}_1(x_{1t}), \ldots, \hat{F}_N(x_{Nt})).
\]

Then, we can write the sample equivalents of $H_\theta$ and $C_\theta$ as

\[
\hat{H}_\theta = T^{-1} \sum_{t=1}^{T} H_t(\theta), \\
\hat{C}_\theta = T^{-1} \sum_{t=1}^{T} C_t(\theta).
\]

We can now base the test on the distinct elements of the testing matrix $\hat{H}_\theta + \hat{C}_\theta$. Given that the dimension of $\theta$ is $p$, there are $p(p+1)/2$ such elements. Under correctness of copula they are all zero. This is in essence the likelihood misspecification test of White (1982). However, he deals with the full but possibly incorrect parametric log-density. So the elements of his testing matrix (he calls them “indicators”) do not contain empirical estimates of the marginal distributions. It turns out that this difference precludes a direct application of his test statistic in our setting.

White (1982) points out that it is sometimes appropriate to drop some of the indicators because they are identically zero or represent a linear combination of the others. When $p = 1$ – the case of a bivariate one-parameter copula – this problem does not arise. Whether it arises in higher dimensional models is a copula-specific question that is not addressed in this paper. Assume that no indicators need be dropped.

Following White (1982) define

\[
d_t(\theta) = \text{vech}(H_t(\theta) + C_t(\theta))
\]

so that the indicators of interest are

\[
\hat{D}(\theta) = T^{-1} \sum_{t=1}^{T} d_t(\theta).
\]

Let $D_\theta = E d_t(\theta)$.

What differs our setting from White (1982) is that nonparametric estimates of the marginals are used to construct the joint density. It is well known that the empirical distribution converges to the true distribution at the rate $\sqrt{T}$ so the CMLE estimate $\hat{\theta}$ that uses empirical distributions $\hat{F}_n$ is still $\sqrt{T}$-consistent.
However, the asymptotic variance matrix of $\sqrt{T} \hat{\theta}$ will be affected by the nonparametric estimation of the marginals. Therefore, the asymptotic variance of $\sqrt{T} \hat{D}_{\theta}$ will also be affected. The proper adjustments of the variance matrix for the general two-step semiparametric estimation are given in Newey (1994); Chen and Fan (2004). Specifically, we will use the variance formula derived by Chen and Fan (2004) for the case when empirical marginal distributions are used in the parametric estimation of copulas.

**Proposition 1** Under the correct copula specification, the information matrix test statistic

$$\mathcal{I} = T \hat{D}' V_{\theta_o}^{-1} \hat{D},$$

where $V_{\theta_o}$ is defined in the appendix, is distributed asymptotically as $\chi^2_{p(p+1)/2}$.

In practice, a consistent estimate of $V_{\theta_o}$ will be used.

4 An application of the test

To demonstrate how the test procedure of the previous section can be applied in practice we test whether the Gaussian copula is appropriate for modeling dependence between an American and an European stock index.

We use the FTSE100 and DJIA close from June 26, 2000 to June 28, 2008. We have 1972 pairs of returns after eliminating holidays. Table 1 contains descriptive statistics of the returns.

An AR-GARCH filter that we apply to the return data accounts for most of the observed autocorrelation in the level and squared returns. The preferred models contain Normal innovations – allowing for Student-t innovations resulted in a relatively high estimate of the degrees of freedom (over 9) and did not improve the fit substantially. Table 2 reports the results of AR-GARCH modeling.

Table 3 contains the results of the testing procedure. The estimated parameter $\theta$, which is just the correlation coefficient in the case of the Gaussian copula in (3), is high, positive and significant. There are two test statistics. One is called unadjusted. It is incorrect because it ignores the fact that the cdf’s were estimated semiparametrically in the first step. The other is called adjusted. This is the statistic that uses the correct variance formula. Note that adjusting for estimation of cdf’s makes the statistic larger. At 5%, we reject the hypothesis that the Gaussian copula is appropriate to model dependence between the two time series.

5 Concluding remarks

Unlike many available alternatives, the test proposed in this paper is simple and easy to implement. Essentially it is a special case of White’s information equivalence test with the complication of a first-step empirical density estimation. However, as such, it also inherits a number of drawbacks.

Horowitz (1994), for example, points out to large deviations of the finite-sample size of the White test from its nominal size based on asymptotic critical values and suggests using bootstrapped critical values instead.

Another complication is the need to evaluate the third derivative of the log-copula density function. Lancaster (1984) shows how one can construct the test statistic without using the third order derivatives.

Clearly all these considerations apply to our test statistic.

6 Appendix

Sketch of proof of Proposition 1. Provided that the derivatives and expectation exist, let

\[ \nabla D_\theta = E \nabla_{\theta} d_t(\theta) \]

and

\[ \nabla \hat{D}_\theta = T^{-1} \sum_{t=1}^{T} \nabla_{\theta} d_t(\theta). \]

Start by MVT for \( \sqrt{T} \hat{D}_\theta \)

\[ \sqrt{T} \hat{D}_\theta = \sqrt{T} \hat{D}_{\theta_0} + \nabla \hat{D}_\theta \sqrt{T}(\hat{\theta} - \theta_0), \quad (7) \]

for \( \tilde{\theta} \) between \( \theta_0 \) and \( \hat{\theta} \). Then,

\[
\sqrt{T} \hat{D}_{\bar{\theta}} = \sqrt{T} \hat{D}_{\theta_0} + \nabla D_{\theta_0} \sqrt{T} (\hat{\theta} - \theta_0) + o_p(1). \tag{8}
\]

Now, Chen and Fan (2004) show that

\[
\sqrt{T} (\hat{\theta} - \theta_0) \to N(0, B^{-1} \Sigma B^{-1}), \tag{9}
\]

where

\[
B = -H_{\theta_0}, \\
\Sigma = \lim_{T \to \infty} \text{Var}(\sqrt{T} A_T^*) \\
A_T^* = \frac{1}{T} \sum_{t=1}^{T} (\nabla \ln c(U_t, V_t, \theta_0) + W_1(U_t) + W_2(V_t)) \tag{10}
\]

Here terms \( W_1(U_t) \) and \( W_2(V_t) \) are the adjustments needed to account for the empirical distributions used in place of the true distributions. These terms are calculated as follows:

\[
W_1(U_t) = \int_0^1 \int_0^1 [I\{U_t \leq u\} - u] \nabla_{\theta, u}^2 \ln c(u, v; \theta_0) c(u, v; \theta_0) dvdu \\
W_2(V_t) = \int_0^1 \int_0^1 [I\{V_t \leq v\} - v] \nabla_{\theta, v}^2 \ln c(u, v; \theta_0) c(u, v; \theta_0) dvdu
\]

So,

\[
\sqrt{T} (\hat{\theta} - \theta_0) = B^{-1} \sqrt{T} A_T^* + o_p(1). \tag{11}
\]

Then,

\[
\sqrt{T} \hat{D}_{\bar{\theta}} = \sqrt{T} \hat{D}_{\theta_0} + \nabla D_{\theta_0} B^{-1} \sqrt{T} A_T^* + o_p(1), \tag{12}
\]

and we have the asymptotic distribution of \( \sqrt{T} \hat{D}_{\bar{\theta}} \):

\[
\sqrt{T} \hat{D}_{\bar{\theta}} \to N(0, V(\theta_0)), \tag{13}
\]

where

\[
V_{\theta_0} = E[d_t(\theta_0) + \nabla D_{\theta_0} B^{-1} (\nabla \ln c(U_t, V_t, \theta_0) + W_1(U_t) + W_2(V_t))] \\
\times [d_t(\theta_0) + \nabla D_{\theta_0} B^{-1} (\nabla \ln c(U_t, V_t, \theta_0) + W_1(U_t) + W_2(V_t))]'.
\]
